WE have received a copy of the proposed Bill to Regulate the Practice of Pharmacy and the Sale of Poisons in Jersey, and cordially welcome it as an effort to put the work of the druggist there more in line with the conditions which control the practice of pharmacy in this country. The Bill provides for the proper qualification of those acting as chemists or druggists, but the qualifications recognised include those of the Schools of Pharmacy of the University of France in addition to those granted by the Pharmaceutical Society of Great Britain or the Pharmaceutical Society of Ireland. A register is to be kept of all those to whom permission to practise has been granted, and it is to state the title or qualification in each case. To prevent hardship the new Act will not apply in these respects to those chemists and druggists who are already practising in Jersey. A further act of grace enables the legal representatives of a chemist or druggist who has practised his profession in the island to continue the business after his death, but it necessitates the employment of an assistant who is in all respects qualified and authorised to act as a chemist and druggist. Provisions which closely follow those in force in this country safeguard the sale of poisons, whether wholesale or retail, and the Bill includes a list of poisons, and the usual precautions are taken to prevent the sale of the more active and dangerous poisons to minors aged less than sixteen years or to persons unknown to the vendor. It is satisfactory to find that preparations used or sold for the destruction of vermin are included in this list. Medicines containing a poison or poisons prepared by a medical man, or by a chemist or druggist when prepared after a medical prescription, are exempt from the restrictions ordinarily affecting the sale of poisons, provided that a copy of the prescription is kept by the vendor. Nothing is said in this connexion of the importance of marking the prescription with a date each time it is brought to the druggist, a small precaution which would be for the public safety in dealings with poisons. The concluding articles of the Bill refer to the penalties incurred by contraventions of the regulations. The proposed Act is so liberal in dealing with vested interests and so essential for the protection of the druggist and the public that it should meet with no opposition and but few amendments.

ELDER BARK AS A DIURETIC.

M. Lemoine, Professor of Clinical Medicine in the Medical Faculty of Lille, has recently revived the practice of employing the elder (sambucus niger) as a diuretic. Some years ago he was much struck with the efficacy of a decoction of elder bark in a case of general anasarca with pulmonary œdema and ascites due to subacute nephritis in which several ordinary diuretics had failed. The first day of the treatment by elder the urine, which had been very scanty, rose to 400 grammes, the next to 1500 grammes, and at the end of a week's treatment to 3500 grammes. Since that time M. Lemoine has had occasion to use this remedy frequently for œdema or ascites due to heart or kidney troubles, and it has almost invariably been successful in increasing the quantity of urine passed. At his request Dr. Combermale has made a series of experiments on animals. He finds that infusions and decoctions of the inner bark are more active than those of the outer bark. Latterly M. Lemoine has employed an alcoholic extract of the inner bark, sometimes prescribing it alone, sometimes alternately with digitalis or caffein, the effects of which it serves to prolong and increase. There do not seem to be any distinct contra-indications to its use and it does not produce any unpleasant head or lung symptoms. It may, however, sometimes cause diarrhœa or increase it if already existing.

POISONING WITH PIPERAZINE.

In the American *Medical News* Dr. Slaughter of Philadelphia relates the case of a young married woman aged thirty-two who, through a druggist's blunder, received one dose of piperazine of twenty grains. Some hours later, when the patient was seen by Dr. Slaughter, she was much cyanosed and in a serious comatose condition. The pupils were much contracted, the pulse gave 50 beats to the minute, and the temperature was 97·4° F. The respirations also were slow and there was low muttering delirium. The tips of the fingers were cyanotic and there was loss of motion but not of sensation in the lower limbs. Cardiac and other stimulants were at once energetically used, while the limbs were elevated and external heat was applied. A stimulating rectal injection was also given and the catheter was used. There was paraplegia, afterwards treated by massage and large doses of strychnia. Recovery was perfect.

APOCYNUM CANNABINUM.

Apocynum cannabinum, which in America is called Indian hemp, has long been used as a diuretic and indeed is included in the United States pharmacopœia. Its value in general dropsy due to renal disease gained for it the name of "the vegetable trocar" from Dr. Rush.[1] Its physiological properties have recently been investigated by Dr. Dortschewski, who agrees with American observers that the most active portion of the plant, from a pharmacological point of view, is the cortex of the root. An extract was prepared from this and diluted with from ten to twenty times its volume of water. Less than 100 cubic centimètres of this diluted extract was sufficient to kill a medium-sized dog. The effect was to increase the blood pressure and to cause the heart's beat to become at first slower, stronger, and reduplicated, but subsequently rapid and irregular until the animal died. The effects were due to the action of the drug on the motor centres of the brain and spinal cord, the slowing of the pulse being caused by the stimulation and its rapidity by paralysis of the pneumogastric centres. The increased blood pressure, too, was due to the contraction of the peripheral arteries from central action. In clinical practice it was found that patients with cardiac mischief could take from five to ten drops three times daily with marked advantage. Larger doses were apt to cause nausea and vomiting.

ESSENTIAL OIL OF GARLIC IN PHTHISIS.

Dr. Séjournet of Revin communicates to the *Union Médicale du Nord-Est* some account of the effects he has obtained by treating phthisical patients with garlic. The preparation he used was the essential oil of garlic, that is to say, the sulphide of allyl, which he mixed with 200 times its weight of sterilised olive oil, the mixture being called by him "scoradine." A cubic centimetre of this was injected under the skin below the spine of the scapula, at first at intervals of some days and afterwards when the patients were able to tolerate it every day. Under this treatment the general condition improved in a marked degree and the local signs of the disease became modified. Sixteen patients have been treated in this way with excellent results.

[1] See THE LANCET, March 13th, 1886, p. 508.

THE HEALTH SECTION AT THE CARDIFF EXHIBITION.—The Cardiff Exhibition, which was opened by Lord Windsor on May 2nd, contains an interesting health section, the exhibits of which have been so numerous that the committee have had to nearly double the extent of the accommodation. It contains several sanitary appliances, and amongst other features may be mentioned the various processes adopted for freezing meat and the destructive distillation of wood. A model hospital is fitted up and the daily working and routine is shown. It is proposed to give a series of lectures on 'First-aid" in connexion with the St. John Ambulance Association. In another section scientific instruments are shown, and although the space is very limited the committee, of which Mr. E. T. Collins, M.R C.S. Eng., is secretary, have succeeded in bringing together an interesting collection. The profits of the exhibition, on which £100,000 has been expended, will be divided between the Cardiff Free Museum, the Free Library, and the charities of the town.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XIX.

The Offensive By-law.—Its Effect on the Private Schools.—More Letters of "Brutus."—The Sorest Point with the Members.—Dr. John Armstrong's Pamphlet.—A General Meeting of the Profession suggested.

ON March 19th, 1824, a manifesto was issued from the Royal College of Surgeons of England, which was stated by the authorities of the corporation to have been promulgated "in pursuance of the duty of the Court of Examiners." This manifesto contained the by-law to which allusion was made in the previous chapter and which was found by Wakley's reforming spirit as well as by his personal interest to be so very offensive. The wording of the by-law was as follows:—

"That certificates of attendance at lectures on anatomy, physiology, the theory and practice of surgery, and of the performance of dissections be not received by the Court except from the appointed professors of anatomy and surgery in the University of Dublin, Edinburgh, Glasgow, or Aberdeen, or from persons teaching in a school acknowledged by the medical establishment of one of the recognised hospitals, or from persons being physicians or surgeons to any of these hospitals."

As has been said, Wakley's first objection to this by-law was that it conferred on the metropolitan hospital surgeons and lecturers an increased authority. It virtually gave them a complete monopoly in the surgical education of the London student, and this at a time when Wakley was attempting to show in the columns of THE LANCET, and making a very successful attempt also, that the metropolitan hospital surgeons were selected upon corrupt principles, and that no one therefore need be surprised if they should be found unable to discharge their duties properly either towards the sick, the student, or the public. From discussing the by-law from this point of view such a disputant as Wakley was bound to pass almost immediately to its more general consideration. We find him at once discussing the *personnel* of the Court of Examiners and the methods which had dictated their election until, by swift retrogression, he reaches the constitution of the College.

The Court of Examiners who had "pursued their duty" in issuing this by-law was constituted as follows:—Sir Astley Cooper, Mr. Abernethy, Sir Everard Home, Sir William Blizzard, Mr. Cline, Sir David Dundas, Mr. Forster, Sir Ludford Harvey, Mr. Lynn and Mr. Norris; and every one of these gentlemen was a past or present lecturer at a hospital school, and directly or indirectly a pecuniary beneficiaire under the working of the new law. The real purpose of the objectionable by-law was, in fact, to aggrandise the hospital surgeon. It was not only that it placed the exceedingly lucrative post of lecturer at his disposal, but it gave him a monopoly. He was not put into competition with the outside lecturers. Here Wakley's personal feelings no doubt dictated his inimical view. He was himself, as we have already said, largely educated at a school, the Webb-street School, attached to the Borough Hospitals, but only informally. Most of the students at this school were young men who were walking the wards of Guy's Hospital or St. Thomas's Hospital, but they were not compelled to take out their anatomy course with the Graingers, who conducted the Webb-street School; on the contrary, at Guy's Hospital Mr. Aston Key and Mr. Bransby Cooper were lecturing in anatomy; while at St. Thomas's Hospital Mr. Joseph Henry Green and Mr. Flint South were prepared to instruct the student in the same subject; and, as an additional facility to the student of the Borough Hospitals, if he had paid his fee as a perpetual student at the school of either hospital he could attend whichever anatomical course he chose. In spite of the embarrassment of riches that is suggested by a choice of four authorised demonstrators at the regular schools it was a fact that the majority of the Borough students joined the Webb-street School, as Wakley had done, for the brothers Edward and Richard Grainger—exceedingly able anatomists—had a reputation as instructors that entirely put in the shade that of the four members of the combined staff of the Borough Hospitals. Consequently many fees found their way to Webb-street that should have gone to the Borough Hospitals. Now the by-law would prevent this. It would make the brothers Grainger mere coaches, whose certificates of attendance had no real value. Similarly, Mr. Joshua Brookes, of the Theatre of Anatomy in Blenheim-street, and Mr. Carpue, whose headquarters were at Dean-street, also in Soho, were deprived of their status as official lecturers.

Now, these men, like the Graingers, were among the finest anatomists in England, and instructed the majority of the students at St. George's and Middlesex Hospitals and many from other less adjacent schools while of the four hospital lecturers Mr. Green alone could be considered a first-class anatomist. Curiously enough Mr. Green's class suffered most under the system of free trade, for the competition of the Graingers, who had more to offer and at a lower figure, had told so severely upon the St. Thomas's School that, according to Wakley, who was in the habit, it must be remembered, of constantly attending the lecture-rooms of all the schools, public and proprietary, Mr. Green's post was becoming a sinecure. This struck Wakley as in no way regrettable, and merely a very proper example of the survival of the fittest, (though the phrase had not then been coined). Therefore he saw in the by-law an unfair attempt to bolster up the incompetent hospital official and give him a monopoly in a lucrative business which he had not had enough wits to keep by his own exertion in fair competition. The hospital official had, in short, to be protected against the outside lecturer. Furthermore, Wakley considered that the authorities of the Royal College of Surgeons of England had betrayed their position by thus sanctioning a piece of legislation so wholly in the private favour of hospital surgeons and so inimical to the interests both of their commonalty and of the students from whom their coffers were repleted. For it must be remembered that not only were the outside schools cheaper to attend, but they were open all the year round, while the anatomical lectures at the hospitals were only delivered during the winter season. The evils arising from a measure condemning the students to attend the lectures of the hospital officials only were, said Wakley, twofold—unnecessary delay and increased expense, for they would be compelled to spend more time in London. He did not consider it reasonable that every student should be put to an expense of over £100 in order to pour money into the pockets of the gentlemen from whom the Court of Examiners were chosen—viz., the hospital lecturers—and whose by-law in their own interest the College was asked to ratify. He expressed his opinion both with voice and pen that the profession as a whole should petition Parliament to abrogate the existing Charter and grant a new one, in which it should be a fundamental principle that any

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., and XVIII. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, and May 2nd respectively.

Digitized by Google

person to whom the power was given of making by-laws should be elected by the whole body of Members and not by each other, as was the case with the Court of Examiners. This was the course of events which led Wakley to inquire into the constitution of the College, to print its charter, and to promise to spare no pains to make clear to the medical profession that he considered the existing authorities of the College to have abused their position. These are the stages by which he passed from a habit of criticising the College as the stronghold of his declared foes, the hospital surgeons, into a deliberate intent to show it as a constitutionally rotten concern, badly behaved, and of evil pedigree.

During the year 1825 letters from "Brutus" were inserted several times and always showed the intimate knowledge of the constitutional history of the Royal College of Surgeons of England that the communication from the same pen which has already been quoted so obviously displayed. The College, "Brutus" maintained, had virtually formed itself out of the old company without any consultation with the Members—i.e., the commonalty—and the spirit of exclusiveness thus immorally and even illegally shown had been imported into the management of the new corporation. The Court of Assistants and Examiners of the Royal College of Surgeons of England, who were placed by the Charter in the position of trustees for the members of the corporation in general, were found to have abused their trust in every direction. Presented by Government with Hunter's splendid anatomical collection, the Museum had been at once rendered by stupid restrictive regulations inaccessible to the Members for eight months in the year, while no attempt to make it more useful to students by supplying a descriptive catalogue had been entered upon. The great John Hunter's work had been accepted by the Court because it was worth a large sum of money; they at once proceeded to render it valueless by withdrawing it as far as possible from all chances of intelligent notice. The Library, which it was often promised should be thrown open to the Members, had been kept for the sole use of the Court of Assistants. The pecuniary status of the College, which was concealed from the Members, whose fees were taken and nothing rendered them in return, was laid bare by "Brutus." Since the year 1797 the receipts of the College upon a moderate calculation must have exceeded £150,000, and of this sum £32,000 must have been appropriated to the private use of the examiners, so that the concealment of the auditors' accounts had obvious reason. The Members who really supported the College entirely by their fees were excluded from all voice in their own affairs; they were obliged to obtain certificates before being examined from certain persons especially chosen by the College for reasons other than their merits; and, lastly, they could only enter their own building by the back door at stated hours.

The publication of these letters aroused great excitement in the profession, and many communications were written to THE LANCET and privately to Wakley in a similar strain, some enlarging on one grievance and some on another, but all persistently dwelling upon the last two in the category extracted from "Brutus's" bitter epistles. It was an impertinence that every Member felt personally that he should be sent round to the back door of his own College; while the greediness and injustice of the by-law with regard to the certificates of attendance at lectures was very keenly felt by many. In particular the pettiest grievance of all, the fact that the front door of the building in Lincoln's-inn-fields was closed to them rankled in the breasts of the Members. From all parts of England the general practitioners wrote to Wakley to complain of this impertinent distinction between themselves and men whose only claim to superiority was in many instances to be found in their relationship to some inept hospital surgeon or the longer purses of the parents who provided them with education. Some of them thought that the history of the Charter was discreditable, and many of them grumbled at the large fees that were exacted from them, but all who put pen to paper on the subject of their College—and it was a large number—based their support of a reforming movement chiefly upon their intention to obtain the right to go into their own College by the front door. One such letter is worth printing if only that it contains a tribute of personal respect that might have inspired Mr. Sampson's opinion of Mrs. Wilfer. "With every sentiment of respect for you, you know, ma'am—vipers really doesn't do you credit," said that *naïf* gentleman, it may be remembered, to his future mother-in-law; and Mr. James Morss Churchill wrote with something of the same simplicity to Sir Anthony Carlisle:—

To Sir A. Carlisle.

SIR,—When you delivered the Hunterian Oration two or three years ago I was one of your hearers, and was exceedingly gratified by it; and it is out of no personal disrespect to you either as a man or as a surgeon that I signify to you my intention of not being present at the next anniversary; for, independently of the detestation with which I view the various disgraceful and arbitrary acts which proceed continually from the corporate body of the College of Surgeons, I consider it extremely degrading to pass down Portugal-street, celebrated only for its stables, butchers' shambles, and dirt, that I may enter the *back* door of a building which has a handsome portal, through which pass none but a self-elected body of about twenty individuals and some of their very particular friends.

I for one protest against such uncalled-for distinctions and thus set an example which I trust will be followed.

I am, Sir, your humble and obedient servant,

JAMES MORSS CHURCHILL.[2]

In the meantime Wakley and his correspondents in THE LANCET were not the only critics of the action of the College of Surgeons in issuing the by-law concerning certificates for students. A pamphlet had been published by a Dr. John Armstrong dealing very roughly with the action of the College in issuing the offending by-law. Dr. John Armstrong was lecturer on the Principles and Practice of Physics at the Webb-street School, where the brothers Grainger were the proprietors and chief lecturers, so that his opinions could not be considered unbiased. The Graingers were the persons most clearly aimed at by the by-law—or rather, to those who believed that the motives of the Court of Examiners in making such a by-law were wholly corrupt the Graingers must have seemed to be the particular individuals most hardly used; therefore their colleague's opinions were necessarily received with caution. Another intimate friend of Dr. Armstrong, a Mr. Bennett, was also a well-known lecturer whose certificates were rendered valueless by the new regulations, and his case is quoted in the pamphlet as one of particular hardship. Dr. Armstrong's work was, therefore, regarded by the College as the outcome of mere partisanship. Wakley said that he saw no reason whatever to doubt the purity of his motives; his only criticism of his ally was that the view taken up by Dr. Armstrong was too narrow. Dr. Armstrong in his pamphlet contented himself with insisting upon the hard measure that had been dealt out to a number of worthy persons, whose income was largely derived from students' fees, by making their lectures practically useless as part of the surgical education of the future Members of the College of Surgeons; while Wakley looked upon this as only a minor point, the larger question being present to him by this time—viz., how the constitutional reform of the College from top to bottom, from hall porter to President, could be best effected. But Dr. Armstrong's pamphlet had its outcome. It placed

[2] THE LANCET, Feb. 11th, 1826.

Digitized by Google

the *pros* and *cons* of one point, if a small one, before a large number of persons, and prepared their minds for the developments now imminent.

Week after week the necessity for reform was urged in THE LANCET. The language might differ, but the sentiments were always the same. The result of these repeated and categorical accusations as well as of the letters of "Brutus" and Dr. Armstrong's pamphlet was to bring to Wakley an enormous mass of letters, showing that the dissatisfaction of the commonalty of the College with their rulers was very real and very widespread. As soon as this evidence reached him that the time was rife for organised resistance he placed himself in the van. Hitherto, as has been said, his opposition to the junto at the head of the College business had been largely a part of his general crusade against the management of the metropolitan hospitals, but when he saw that a large number of his readers were deeply stirred by the wrongs they had received at the hands of the Royal College of Surgeons of England his treatment of the subject became more serious and much more comprehensive. Instead of seeing in the abuses at the College a mere confirmation of the fact that self-elected rulers—whether presiding at lecture-room, operating-table, or examining board—were under strong temptations not to do their duties, as they were answerable to no one but themselves and all were in the same boat, he became aware that the profession at large was deeply moved at the way in which they were treated and in which the College of which they were mostly members was governed, and he pledged himself to a definite course—namely, to the procural by all constitutional methods of agitation of some measures of redress. In January, 1826, a suggestion was made in THE LANCET that a meeting of the profession should be held to determine on a plan of campaign, the suggested course being to petition the Crown to grant a new Charter or to appoint a Royal Commission to inquire into the working of the Charter granted by the late King in 1802.

(To be continued.)

ANNUAL REPORT FOR 1894 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

III.[1]

THE duties of supervision which devolve upon the County Council in respect of sanitary administration over the entire area governed by the forty-three metropolitan vestries necessarily occupy very much of the attention of the Council and find almost constant employment for its Public Health Committee. In their endeavours to secure that the conditions under which milk was sold during 1894 in London were such as would prevent risk of contamination difficulties were frequently experienced by the committee from itinerant milk vendors. These persons sell milk in the streets during the day and in the evening take what remains to their homes, often consisting of single rooms, where the conditions are but little conducive to cleanliness. In such rooms, the means for washing or scalding milk-cans being absent, any remaining milk is allowed to stand in the cans through the night, exposed to the foul atmosphere of a crowded sleeping apartment, and is distributed next day mixed with the morning's fresh supply. These hawkers are migratory in their habits and their homes can with difficulty be found; they generally contrive to evade registration. Offensive trades come in for a large share of the inspector's attention—the businesses of cattle slaughterer, knacker, marine-store dealer, brick-burner, and gas manufacturer being mentioned in the report as having received special attention during the year. The condition of the Regent's and Grand Junction Canals was brought prominently before the Council, but little amendment seems to have hitherto been effected because of the adverse opinion of counsel as to the legal powers of the authorities concerned. A considerable number of schemes were either initiated or advanced a stage during the year under Parts I. and II. of the Housing of the Working Classes Act in respect of unhealthy areas. The committee were actively engaged in dealing with questions of the reconstruction and rearrangement of the Boundary-street area and in contributing to the expenses of schemes under Part II. of the Act, undertaken by the various sanitary authorities. In particular, progress was made during 1894 in dealing with improvement schemes connected with Brooke's-market, Holborn, Ann-street, Poplar, and Mill-lane, Deptford, all of which had been previously sanctioned by the Council. The Millbank Prison site, consisting of about ten acres of land, was also purchased by the Council at the price of £2500 per acre for the purposes of Part III. of the Housing of the Working Classes Act. Three hundred and seventy-six presentations were made during the year in respect of houses unfit for human habitation. In all cases orders were obtained for the closing, demolition, or improvement of these properties, and only 12 cases remained undealt with at the end of the year. The Public Health Committee devoted much attention to the question of workmen's train service in the metropolis. At a conference of representatives of the railway companies an attempt was made to secure an extension in the time of arrival of the workmen's morning trains at the termini and also the removal of existing restrictions against the use of return workmen's tickets except by special trains and after certain hours. Having failed in their attempts to obtain more than trifling concessions from the companies, the committee reported that further Parliamentary inquiry was necessary in order to settle whether any and what amendments were required in the Cheap Trains Act, and they recommended the Council forthwith to petition Parliament for an inquiry into the whole subject of extension of the cheap train system for the working classes. The condition of the London bakehouses was specially reported on by Mr. Shirley Murphy during the year. The Public Health Committee were satisfied on review of their medical officer's report that the law with reference to bakehouses requires amendment. They recommended that the central metropolitan authority rather than the vestries should have charge of the bakehouses of London and that the Council should be empowered by Parliament to make by-laws for the proper regulation of bakehouses. The food-supply of the metropolis appears to be satisfactorily kept under supervision by the vestries. Seizures were made during 1894 in a large number of districts of food consisting of meat, fish, vegetables, and fruit, and the persons selling such unsound commodities were in most cases fined. In the course of the year the medical officer of health of Islington investigated the question of the manufacture of ice-creams and of the conditions under which this article of food is prepared by the Italian vendors who habitually hawk it in the streets during hot weather. Specimens of ice-creams thus sold, and of the water used for washing the glasses in which the ice-cream is served, were found by Dr. Klein to contain, amongst other things, the "bacillus coli"—a normal inhabitant of the bowels of men and other animals! In December, 1894, Mr. Shirley Murphy presented a report to the Public Health Committee, showing the provision existing in the several metropolitan districts for the disinfection and destruction of infected articles and for the temporary shelter of persons during disinfection of their houses which had been contaminated by infection. The report gives account of twenty out of the thirty-four districts which had already made such provision, and also speaks of other districts which had taken the initiatory steps for providing such safeguards in the near future. As regards hospital accommodation for infectious diseases Mr. Shirley Murphy reports that nearly 18,000 persons suffering from fever, diphtheria, or small-pox were in the course of 1894 removed from their homes to the various hospitals of the Metropolitan Asylums Board, that 5000 convalescent patients were transferred to the Northern and Gore Farm Hospitals, and that about an equal number of patients were returned to London from those hospitals. The accommodation for scarlet fever was found sufficient, but that for diphtheria was insufficient during this year, and consequently much delay occurred in the removal of

[1] Nos. I. and II. appeared in THE LANCET of May 2nd and 9th.

Digitized by Google

sufferers from enteric fever and diphtheria, if, indeed, many of them were not unavoidably left to be treated in their own homes.

Arrangements are now in progress for the erection of fever and diphtheria hospitals at Shooter's-hill, Hither-green, and Lower Tooting, containing about 500 beds apiece. When the additional hospital buildings now in progress have been completed it is contemplated that the Metropolitan Asylums Board will possess accommodation for 6000 fever and diphtheria patients, exclusively of that provided for small-pox. Additional land at Long Reach has also been acquired near the hospital ship as a site for a small-pox isolation hospital. In connexion with the spread of small-pox by vagrants, which subject has been under the consideration by the committee since the beginning of 1893, a conference was held at the County Hall in July, 1894, and was attended by delegates from thirty-three London vestries and thirty-two extra metropolitan sanitary authorities. After discussion a series of recommendations were adopted with a view of limiting the spread of infectious disease by means of tramps and of providing for the more satisfactory regulation of the persons inhabiting common lodging-houses. In regard to the question of metropolitan water-supply Mr. Shirley Murphy has important observations for the consideration of the Council not less than of the consumers of water themselves. He states the opinion that examination of water delivered by any filter at intervals not shorter than a month affords but an inadequate test of the continued efficiency of filtration throughout the year. So long as London is so largely dependent on river supply for its drinking water it is obvious that examinations are requisite at much shorter intervals than a month, and it would appear to be the duty of the London County Council as the chief guardian of the health of the metropolis to arrange for a much more frequent examination of its water-supply.

During the year 1894 the London Building Law was consolidated and amended. The Act requires that for the future there shall be provided for the due ventilation and lighting of basements in rear of every building an open space of not less than 100 square feet, free from any erection above the level of the pavement. The elevation of every domestic building is, moreover, to be limited by the extent of the open space at the rear, so that its height shall not exceed twice the distance from the rear of the building to the boundary of the open space. Domestic buildings may be erected under special provisions on the site of similar buildings existing before 1894, which had less than the rear space prescribed by this Act, provided that no more ground is occupied by the new buildings than that which had been covered by the buildings previously existing.

In bringing to a close our notice of Mr. Shirley Murphy's excellent report we regret that we have no space for remarks upon any of the eleven appendices which form part of the document before us. We can only hope that these appendices, each of which is a complete report in itself, will receive adequate circulation, for they possess in almost every instance, far more than merely local interest.

THE PRIVY COUNCIL AND THE APOTHECARIES' HALL OF IRELAND.

IN THE PRIVY COUNCIL.

In the Matter of the Medical Acts 1858 to 1886 and in the Matter of an Application by the Apothecaries' Hall of Ireland for the Appointment of Examiners to Assist at the Qualifying Examinations which are held by the said Hall.

THIS case was heard on Monday, May 11th, at eleven o'clock in the Privy Council Chamber, Downing-street. The Members of the Privy Council were the President of the Council (the Duke of Devonshire), Lord Macnaghten, Lord James of Hereford, and Lord Rathmore. The Apothecaries' Hall was represented by Mr. R. B. Haldane, Q.C., M.P., and Mr. B. S. Foster; the General Medical Council by Sir Robert Reid, Q.C., M.P., and Mr. Muir Mackenzie. Several members of the General Medical Council were present, including the President (Sir Richard Quain), Dr. Thorne Thorne, and Dr. Glover. The proceedings were not prolonged. Mr. Haldane spoke for two hours on the history of the case as detailed in the minutes of the General Medical Council, a pretty full *précis* being in the hands of the court. His contention was that the Apothecaries' Hall had done its best under difficult circumstances; that on the admission of the Inspector and Visitor of the Council the examinations were improving, and that the Visitor was in error in saying that a certain candidate had passed who had not passed. He did not attach much importance to the allegations of malice in the pleadings of the Hall against the Royal College of Physicians of Ireland but to the great claims of the Hall examination as meeting the case of those who were intended for general practice in Ireland, and he maintained that if the Council would appoint examiners as desired the prosperity of the Hall would revive, and that it was for the interest of Ireland that it should do so. He showed that the action of the General Medical Council at the last meeting would destroy the power of the Hall to place its Licentiates on the Register—a statement which seemed to surprise Lord James of Hereford and Lord Macnaghten, who questioned Mr. Haldane on the subject. They were soon convinced by his reference to the Acts that it was so.

On the conclusion of Mr. Haldane's speech Lord Macnaghten asked him if the best course would not be for the Hall to make a further application to the General Medical Council for examiners, not confining the Council merely to surgical examiners. Mr. Haldane said he must consult his clients. Lord Macnaghten made a similar appeal to Sir Robert Reid, who begged in a few sentences to indicate the object and views of the General Medical Council, the drift of which was that the Council's prime object was to uphold the standard of medical education. Mr. Haldane then announced the willingness of the authorities of the Apothecaries' Hall to make a renewed application in the form suggested by their Lordships. Sir Robert Reid and Mr. Muir Mackenzie conferred. Though they could not pledge the General Medical Council they agreed to represent to it the views of the Court. Lord Macnaghten expressed the hope that such a course would succeed with the General Medical Council. "We all know," he said, "its familiarity with these questions and the great respect in which it is held by the public. There has evidently been a slight misunderstanding as to the facts which have now been placed in a clearer light. It is admitted that the examinations are improving, and the Council will have a freer hand over them if it pleases to require the nomination of other than surgical examiners. If it can settle this question it will relieve us from a delicate and difficult situation. At the same time the question will stand over for our further consideration should it not be arranged by the Council at its approaching meeting."

THE ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1894.

[SECOND NOTICE.[1]]

WHILE the chief causes of admission among the European troops in India were venereal diseases and ague, causing 34 and 27 per cent. respectively of the total sickness, the chief causes of mortality were enteric fever, cholera, hepatic abscess, and injuries. Enteric fever gave rise to 36 per cent. of the total deaths and cholera to 13 per cent. We have already described and commented upon the facts connected with the lamentable prevalence of venereal diseases. The Sanitary Commissioner's report contains a good deal of valuable information on the subjects of enteric fever, cholera, malarial fever, dysentery, and hepatic abscess, and we now propose to deal with some of the more salient points of the report in respect of these diseases.

In all three Presidencies enteric fever heads the list of causes of death among British troops, and in Bengal and Bombay the ratio was higher in 1894 than the average of the decennium. Let us see whether any light can be thrown on the subject of enteric fever from general conditions or

[1] The First Notice was published in THE LANCET of May 9th, 1896.

Digitized by Google

etiological considerations before speaking of any assigned specific cause. Among the large stations with a strength of over 1000 we find that enteric fever caused a mortality of 15·23 at Mhow, 14·20 at Meerut, 11·96 at Peshawar, and 8·01 at Lucknow per 1000 respectively, with smaller rates at other stations. The disease is very widely distributed in India. The following table shows that the ratios for European troops are very unlike those for native troops and prisoners.

	1882-91.		1894.	
	Admissions.	Deaths.	Admissions.	Deaths.
European troops ...	14·7	4·13	20·9	5·75
Native troops	0·3	0·09	0·3	0·05
Gaol population ...	0·2	0·10	0·4	0·13

These ratios are obtained from large numbers, they are consistent with one another, and the facts they set forth have been repeated from year to year over such a period of time as to leave no doubt of their substantial correctness. In the case of native soldiers necropsies are rarely obtainable, but among prisoners the cause of death is verified in this way in nearly every fatal case. Moreover, the total mortality from fever in the European army is not that, but considerably less than that, of the native army, and the difference cannot, therefore, be accounted for by a mere matter of diagnosis. The question of the immunity, or apparent immunity, of natives of India has been long recognised and differently accounted for. This immunity, it may be added, was maintained by the native contingent during our campaigns in Egypt. It is but part of a bigger question, for the Arabs of Algeria and the natives of other countries enjoy a similar immunity. Mr. Hankin states, as the result of his observations, that the natives of India appear to be naturally insusceptible to enteric fever. The three principal views that have been put forward, according to the Sanitary Commissioner's report, are: (1) inherent racial immunity; (2) acquired toleration by exposure to, and a continuous but gradual imbibition of, the poison; or (3) the protective influence of the disease acquired in early life, but of the possible truth of this assumption there is really no reliable evidence. The results of the experimental researches of Sanarelli are quoted to show that it is possible that the natives of India may not be really immune; but that, by the constant imbibition of bacterial toxic fluids, they may have attained intestinal tolerance, and that, therefore, fatal fevers among them may often be in reality cases of enteric fever without intestinal lesions; but in that case we do not see how the nature of the fever can be really determined; it must remain a reasonable conjecture insusceptible of actual proof.

As regards the general contributory causes and conditions to this disease what has been pretty well established amounts to this: that enteric fever is very prevalent among Europeans in tropical and sub-tropical climates; that it has seasonal periods of manifestation, its maxima of prevalence coinciding with the maxima of temperature, the disease, for example, occurring earlier in the plains of India than in the hills; and that as regards the age of its subjects youth and immaturity and recent arrival in those climates are powerful predisposing causes to attack. But when we have said all this there still remains an essential factor to be added without which the disease does not appear, and this is now practically assumed by all bacteriologists to be the Eberth-Gaffky bacillus. The question narrows itself down, then, into the inquiry as to the life-history of this parasite and how it gains an entrance into the human system. Mr. Hankin has by his researches thrown considerable light on the origin of some mysterious cases and outbreaks in India. Some bacteriologists hold that the bacillus is constantly present in the stools of enteric fever patients after the second week of the disease, and that it maintains its identity and can also be recognised outside the body—in water, for example, contaminated by animal dejecta. In a very careful review of the recent literature on this subject the Sanitary Commissioner shows, however, that considerable difference of opinion still exists among bacteriological authorities and that there are many points which yet require to be cleared up before we can be said to have exhausted our knowledge of the subject and of the causation of typhoid fever. Professor Wright of Netley and Surgeon-Major Semple, for example, have pointed out in the pages of THE LANCET[2] that the typhoid fever bacillus was detected in the urine of enteric fever patients in six out of seven cases examined, and they accept the conclusions of Sanarelli and Wathelet that enteric fever is a blood infection and that the bacillus of Eberth is rare in the stools. Of course, if these observations be subsequently confirmed this source of infection will have to be recognised and guarded against. The water theory of enteric fever, as of cholera, has the largest amount of evidence in its favour; but in the meantime the Sanitary Commissioner contends that it may not be the whole truth and that the lesson to be learned is that we cannot be too careful of attention to cleanliness in all things and of guarding every avenue of approach, not only from enteric fever but from any filth disease. The hygienic condition of our cantonments may be excellent, but that of the native bazaars and villages and of every place, indeed, accessible to the soldier outside cantonment limits may be, and really is, quite the reverse. The difficulty that has to be accounted for, however, is the relatively small amount of enteric fever among the children and women, who consume both water and milk, and the large amount of it among officers, who do not usually consume these or the beverages and products of the native bazaars of which they are not usually frequenters as are the men. With the number of skilled inquirers available in India, supplemented by the researches of bacteriologists, we may fairly anticipate some fresh additions to our knowledge of the nature and causes of this fever which annually gives rise to such a great drain on the young manhood of the European force in that country.

With regard to cholera we may say that in Section 6 of the Report there is a very full and excellent analysis of the views regarding causation of cholera current at the time of Professor Koch's memorable visit to India and subsequently to that date. We may commend this to the perusal of those of our readers who are interested in the study and desirous of obtaining a good summary of the recent advances which have been made in the etiology of cholera.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held on May 6th, at 25, Grosvenor-street. Mr. Timothy Holmes, Vice-President, occupied the chair in the unavoidable absence of Mr. George Pollock, President.

The minutes of the last meeting were read and confirmed. Mr. H. Percy Dunn, honorary secretary, reported that, in answer to the resolution forwarded to the President of the College in reference to the admission of reporters to the meetings of the Fellows he had received a reply to the effect that the Council had already decided to admit reporters to these meetings.

The subject of the direct representation of Members of the College on the Council then came up for consideration in connexion with the adverse resolution adopted at the March meeting of the Council. It was ultimately agreed that the following resolution should be forwarded to the President of the College:—

"The Committee of the Association of Fellows of the Royal College of Surgeons of England regrets that the Council of the College should not have seen its way to adopt the resolution passed by a large majority at the meeting of the Fellows on Jan. 2nd, and trusts that the opinion of the Fellows generally on this important subject may be ascertained as agreed upon at the meeting of the Council of the College held on Feb. 11th."

The Honorary Secretary reported that he had received a communication on the foregoing subject from Mr. Dickinson, honorary secretary of the Society of Members, and it was agreed to acknowledge the letter and to state that the Committee did not see its way at the present moment to suggest any course of action.

The vacancies likely to arise upon the Council in July next were then considered. Mr. Norton stated that he did not intend to come forward as a candidate this year. Several

[2] THE LANCET, July 27th, 1896.

Digitized by Google

other Fellows were mentioned as probable candidates, but it was agreed that the further consideration of the subject should be deferred till the next meeting of the Committee on May 18th.

This concluded the business of the meeting and the Committee adjourned.

THE HISTORY, METHODS, HINDRANCES, EXPENDITURE, AND POLICY OF THE CIVIL RIGHTS DEFENCE COMMITTEE.

(Concluded from p. 1306.)

EXPENDITURE.

THE Civil Rights Defence Committee, although warmly supported in many quarters by the medical profession, has never at any time been in receipt of funds that would enable the committee to take the first step of application for special leave to appeal to the Judicial Committee of the Privy Council and has been compelled either to remain inactive or to expend the funds already received in renewed appeals, each of which has produced an insufficient return. Of the amounts received £84 were paid in preliminary legal expenses incurred in Trinidad and in this country and in the expenses of preparing the petitions for special leave to appeal, which are ready to be lodged. The expenses of the office, clerical assistance, postage, canvassing for signatures to memorials, printing, and other essential matters extending over a period of two years have been considerable and have made large inroads into the funds subscribed. There is an account still due to the printers, and the operations of the committee are hampered by the want of adequate funds. Great economy has been practised in all the expenditure incurred by the committee, letters and circulars wherever possible being delivered by hand and as strict a supervision as possible being exercised over printing and clerical expenses. Mr. Anderson's work for the committee has been entirely gratuitous, and advantageous arrangements were made with Mr. H. Anderson, solicitor of the committee, for office accommodation and clerical aid in his office at 5, Mitre-court, Temple, where the committee sits *de die in diem*, and from which all communications and reports are dated and issued. An Ellam's duplicator was purchased for three guineas enabling the committee to produce many circulars very cheaply. Still, it has been impossible without arresting the progress of the movement to stint the supply of reports, memorials, and other publications, which are essential for the creation of a public opinion favourable to the views of the committee. It is only now that the past outlay in printing is beginning to bear fruit in publicity, it is only by such publicity as that which is now being striven for and obtained that interest can be aroused, and it is only when interest is fully aroused that the general and large subscriptions necessary for the successful prosecution of the various appeals promoted by the committee can be received.

POLICY.

It was explained in the article which appeared in THE LANCET on Feb. 29th on the "Objects and Aims of the Civil Rights Defence Committee" that—

1. The primary purpose for which the Civil Rights Defence Committee was formed was to assist Mr. R. B. Anderson to appeal to the Privy Council for the reversal of the illegal judgments and orders of Colonial judges which remain in force and control his personal liberty, preventing him from returning to Tobago to carry on his practice, collect his debts, dispose of his property, or in any way satisfactorily to settle his affairs—judgments and orders which have been emphatically condemned by Royal Commissioners as "judicial persecution" and "a public danger."

2. The affirmation by the Court of Appeal of Lord Coleridge's decision against Mr. Anderson when a Middlesex special jury had found a verdict in his favour for £500 damages in the action "Anderson *v.* Gorrie and others" has rendered it necessary for the Civil Rights Defence Committee to appeal to the House of Lords to set aside this judgment. The decision renders nugatory not only the stipulations in Magna Charta and the Bill of Rights for the personal liberty of the subject, but the professional rights of medical men conferred by their diplomas whereby they have hitherto been able to pursue their calling in peace, to enjoy the right of recovering their fees for medical attendance in courts of law and to determine for themselves whether they shall attend or not attend, continue or discontinue, attendance in any particular case. The enjoyment of these rights is now made subject to the will and pleasure of Her Majesty's judges, and for any violation of them, however wilful and malicious, committed by a judge no remedy at law will exist.

3. In the event of the decision of the House of Lords upholding the decision of the Court of Appeal the Civil Rights Defence Committee must resort to Parliament for the amendment of the law and for compensation to Mr. Anderson for the unprecedented wrongs he has suffered. A petition to Parliament has been prepared and, if necessary, will be presented in due course by Lord Stamford at the bar of the House.

4. With the view of laying the foundation of a favourable opinion in Parliament and to enlist the sympathies and aid of individual members the Civil Rights Defence Committee arranged for a conference, which was held in the House of Commons on Aug. 29th, 1895. The result was so encouraging that memorials to Members of Parliament have been drawn up for signature by constituents, and are being widely circulated through the agency of friends and with the coöperation of the British Medical Association and its branches.

5. In order to leave no avenue of justice unexplored Mr. R. B. Anderson submitted to the committee a petition to the Queen which he had drawn up, and after very full discussion the committee decided not to fetter his discretion in the matter. Accordingly the petition was sent in and an answer has been received which evades the question really at issue, and which will necessitate further steps.

6. Various public bodies have been approached for the purpose of securing their coöperation and representation on the committee. The bodies at present represented are the British and West Indian Alliance, the West Indian Union, the Royal College of Surgeons of England, the British Medical Association, the Association of Fellows of the Royal College of Surgeons of England, the West London Divisions of the London and Counties Medical Protection Society, and quite recently the Medical Defence Union. The Royal College of Physicians of London, the Apothecaries' Society, the University of London, and the General Medical Council were applied to, but have not responded to the appeal. The Civil Rights Defence Committee still entertains a hope that when these bodies come to understand how the decision of the Court of Appeal affects the professional rights which they guarantee every day, a different result will be obtained.

7. Efforts have been made and will continue to be made to enlist the more active support of the public press. To the medical journals and to some of the weekly and daily papers, to provincial and colonial organs of opinion, and to some of the reviews the committee has been greatly indebted for the insertion of articles and appeals. Quite recently the *Echo* has inserted articles and opened its columns to a correspondence upon Mr. Anderson's case. The *Westminster Review* has dealt with the doctrine of judicial immunity in an exhaustive manner, and in addition to previous articles we have published in the columns of THE LANCET the present series of articles which have, we trust, fully elucidated the whole scope and plan of operations of the Civil Rights Defence Committee. The circle of interest is undoubtedly widening and a full awakening of the public conscience is anticipated at no very distant date. In evidence of this it may be mentioned that only on Friday, May 8th, the Hardwicke Debating Society, which is the chief barristers' debating society and represents the four Inns of Court, engaged in a formal debate on the following resolution, moved by Mr. Copeland and seconded by Mr. Candy, Q.C.

"That the modern interpretation of the law of judicial immunity is mischievous and dangerous, is an encroachment on the liberty of the subject, and ought to be revised." In the course of his speech Mr. Candy said that no more suitable case than that of Anderson *v.* Gorrie could be found for appeal to the House of Lords, and that it is one which justified an appeal to the public for funds. The whole debate turned on Mr. Anderson's case, and the resolution was carried with only two dissentients.

8. Other measures to arouse public sympathy and interest have been undertaken both by Mr. Anderson and the Civil

Digitized by Google

Rights Defence Committee. Operatives in the printing trade and other businesses and political clubs have been addressed, and through their aid the publications of the committee are being widely circulated. Other steps are proposed The organisation of public meetings fully reported in the press ought to bring the work of the committee to a successful issue, since there is but one side to the case, the other being compounded of *vis inertiæ*, *non possumus*, and dogged resistance to the claims of justice. It is in view that public meetings shall be held first in East Islington and Wandsworth, and afterwards at the Mansion House with the coöperation of City guilds, and then throughout the country.

THE SOUDAN CAMPAIGN.

BEYOND the fact of the intended despatch of Indian troops to garrison Suakin and Tokar and the active progress of the preparations on the Nile stations for the anticipated advance on Dongola there is but little to chronicle. We have pointed out the suitability in all respects of our Indian Army for service in Egypt. The native troops are admirably fitted for the climate to begin with, and both in their own country and on previous occasions in Egypt have maintained a high standard of health and efficiency during campaigns in the hot weather, besides being in point of training, gallantry, and discipline excellent soldiers. It is intended that the garrisons of Suakin and Tokar shall consist of these Indian troops and one Egyptian battalion, the remainder of the Egyptian force at those places proceeding to Wady Halfa to form hereafter part of the Dongola expeditionary force. The Indian contingent is a mixed force, consisting of a regiment of Bengal infantry, with a Sikh regiment, the 1st Bombay Lancers, a native mountain battery, and a section of Madras Sappers and Miners. This force will be accompanied by the 31st and 32nd Bombay Native Field Hospitals and the principal medical officer will be Surgeon-Colonel Calthrop, an officer of experience in the field. It is stated that the Indian contingent is for purely defensive purposes and will simply hold the stations whither they are proceeding; but if their services should be subsequently required for field purposes elsewhere they are sure to prove efficient and may be expected to give a good account of themselves.

As far as the Dervishes are concerned the Anglo-Egyptian force on the Nile is allowed to remain quiet and unmolested in making and perfecting their arrangements for the subsequent advance. The different stations are well provided with hospital accommodation, the railway is progressing, and arrangements are being made for the transport of the sick and wounded. The inaction of the Dervishes is attributed to different reasons, but nothing reliable is known about their intended operations; it is all conjecture. Meanwhile the heat is intense and very trying—114° F. in the shade and 128° in tents—but the health of the force continues to be quite as satisfactory as could be expected.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6726 births and 3858 deaths were registered during the week ending May 9th. The annual rate of mortality in these towns, which had been 19·5 and 18·4 per 1000 in the two preceding weeks, rose again to 18·5 last week. In London the rate was 17·9 per 1000, while it averaged 19·0 in the thirty-two provincial towns. The lowest rates in these towns were 12·3 in Portsmouth, 12·7 in Gateshead and in Swansea, 13·3 in Croydon, and 13·8 in Nottingham; the highest rates were 22·0 in Preston, 22·8 in Birmingham, 23·1 in Manchester and in Plymouth, 25·9 in Burnley, and 31·4 in Salford. The 3858 deaths included 622 which were referred to the principal zymotic diseases, against 701 and 641 in the two preceding weeks; of these, 225 resulted from measles, 205 from whooping-cough, 74 from diphtheria, 53 from diarrhœa, 40 from scarlet fever, 25 from "fever" (principally enteric), and not one from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Portsmouth, Nottingham, and Swansea; and the highest rates in West Ham, Birkenhead, Manchester, Salford, and Burnley. The greatest mortality from measles occurred in London, Bristol, Manchester, Burnley, Sunderland, and Birkenhead; from scarlet fever in Huddersfield; from whooping-cough in Halifax, West Ham, Croydon, Manchester, and Salford; and from "fever" in Halifax. The 74 deaths from diphtheria included 41 in London, 6 in West Ham, 6 in Birmingham, 5 in Manchester, and 3 in Burnley. No fatal case of small-pox was registered either in London or in any of the provincial towns. There were 15 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 9th inst., against 16 and 13 at the end of the two preceding weeks; 5 new cases were admitted during the week, against 4, 8, and 3 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2527, against 2527, 2534, and 2523 on the three preceding Saturdays; 238 new cases were admitted during the week, against 236 in each of the two preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 287 and 292 in the two preceding weeks, declined again to 260 last week, and were 68 below the corrected average. The causes of 63, or 1·6 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Oldham, Bradford, Leeds, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·9 and 19·0 per 1000 in the two preceding weeks, further declined to 18·9 during the week ending May 9th, but was 0·4 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 16·8 in Greenock and 17·1 in Edinburgh and in Perth, to 20·6 in Dundee and 22·1 in Paisley. The 552 deaths in these towns included 25 which were referred to whooping-cough, 14 to "fever," 13 to diarrhœa, 11 to measles, 3 to diphtheria, 3 to scarlet fever, and not one to small-pox. In all, 69 deaths resulted from these principal zymotic diseases, against 67 and 76 in the two preceding weeks. These 69 deaths were equal to an annual rate of 2·4 per 1000, which was 0 6 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 30 in each of the two preceding weeks, declined to 25 last week, of which 17 occurred in Glasgow, and 7 in Aberdeen. The deaths referred to different forms of "fever," which had been 4 and 9 in the three preceding weeks, further rose to 14 last week, and included 6 in Glasgow, 4 inEdinburgh, and 2 in Dundee. The 11 fatal cases of measles corresponded with the number in the preceding week, and included 7 in Glasgow and 3 in Dundee. The deaths referred to scarlet fever, which had been 10 and 6 in the two preceding weeks, further declined to 3 last week, of which 2 occurred in Aberdeen. The 3 fatal cases of diphtheria slightly exceeded the numbers recorded in recent weeks. The deaths referred to diseases of the respiratory organs in these towns, which had been 120 and 88 in the two preceding weeks, rose again to 110 last week, and were 12 above the number in the corresponding week of last year. The causes of 26, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 20·6 to 23·7 per 1000, declined again to 21·9 during the week ending May 9th. During the past six weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 18·9 in London and 17·6 in Edinburgh. The 147 deaths registered in Dublin during the week under notice showed a decline of 12 from the number in the preceding week, and included 13 which were referred to the principal zymotic diseases, against 4 and 10 in the two

* Including 44 cases of membranous croup.

† Including deaths from membranous croup.

Digitized by Google

preceding weeks; of these, 7 resulted from "fever" (principally enteric), 3 from scarlet fever, 2 from diarrhœa, 1 from diphtheria, and not one either from small-pox, measles, or whooping-cough. These 13 deaths were equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 3·5 in London and 1·5 in Edinburgh. The 7 deaths referred to different forms of fever exceeded the number recorded in any week since the end of 1894. The fatal cases of scarlet fever, which had been 1 and 6 in the two preceding weeks, declined to 3 last week. The 147 deaths in Dublin last week included 21 of infants under one year of age, and 29 of persons aged upwards of sixty years; the deaths of infants showed a further decline from recent weekly numbers, while those of elderly persons corresponded with the number recorded in the preceding week. No inquest cases, and only 1 death from violence, were registered; and 47, or nearly a third, of the deaths occurred in public institutions. The causes of 12, or more than 8 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING APRIL, 1896.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during April in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 7·5 per 1000 of the population, estimated at 4,435,955 persons in the middle of this year. In the three preceding months the rates had been 10·3, 8·8, and 8·4 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in Fulham, Stoke Newington, St. Martin-in-the-Fields, Strand, and Woolwich; while they showed the largest excess in Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Camberwell, Greenwich, Lee, and Plumstead. The prevalence of small-pox in London showed a slight decline from that in the preceding month, the 22 cases notified including 4 in Kensington, 3 in Plumstead, 2 in St. Pancras, 2 in Hackney, and 2 in the Port of London sanitary areas. The Metropolitan Asylum Hospitals contained 10 small-pox patients at the end of April, against 68, 45, and 33 at the end of the three preceding months; the weekly admissions averaged 4, against 13, 6, and 7 in the three preceding months. The prevalence of scarlet fever in London showed a slight decline during April; this disease was proportionally most prevalent in Hackney, Bethnal Green, Whitechapel, St. George-in-the-East, Newington, Rotherhithe, Lee, and Plumstead sanitary areas. The Metropolitan Asylum Hospitals contained 2464 scarlet fever patients at the end of April, against 2814, 2867, and 2688 at the end of the three preceding months; the weekly admissions averaged 208, against 282, 258, and 234 in the three preceding months. The prevalence of diphtheria in London during April showed a marked decline from that recorded in recent months; among the various sanitary areas this disease showed the highest proportional prevalence in Holborn, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Camberwell, Greenwich, and Plumstead. There were 713 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of April, against 682, 715, and 704 at the end the three preceding months; the weekly admissions averaged 89, against 99 in each of the two preceding months. The prevalence of enteric fever in London showed a slight increase upon that recorded in the preceding month; this disease was proportionally most prevalent in Holborn, Shoreditch, Mile End Old Town, and Bermondsey sanitary areas. Erysipelas was proportionally most prevalent in St. Giles, St. Luke, Shoreditch, Bethnal Green, and Rotherhithe sanitary areas. The 19 cases of puerperal fever notified during April included 4 in Lambeth, 2 in Paddington, 2 in Kensington, and 2 in Islington sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, May 2nd, the deaths of 7951 persons belonging to London were registered, equal to an annual rate of 18·7 per 1000, against 18·4, 20·0, and 19·4 in the three preceding months. The lowest death-rates during April in the various sanitary areas were 10·0 in Stoke Newington, 11·0 in Hampstead, 13·3 in Plumstead, 13·4 in Lewisham (excluding Penge), 14·5 in Lee, and 14·8 in St. George Hanover-square; the highest rates were 23·0 in Limehouse, 24·1 in Bethnal Green, 24·3 in Bermondsey, 25·1 in Woolwich, 26·5 in Strand, 26·8 in St. Saviour Southwark, and 29·2 in St. Luke. During the five weeks of April 1690 deaths were referred to the principal zymotic diseases in London; of these, 750 resulted from measles, 580 from whooping-cough, 206 from diphtheria, 71 from scarlet fever, 49 from diarrhœa, 31 from enteric fever, 1 from an ill-defined form of continued fever, and 2 from small-pox. These 1690 deaths were equal to an annual rate of 4·0 per 1000; among the various sanitary areas the lowest death-rates from these diseases were recorded in St. George Hanover-square, Westminster, Hampstead, Strand, City of London, Whitechapel, and Lee, and the highest rates in Chelsea, St. Luke, Bethnal Green, St. Olave Southwark, Bermondsey, Greenwich, and Woolwich. The 2 fatal cases of small-pox were 3 below the corrected average number in the corresponding periods of the ten preceding years; 1 belonged to Holborn and 1 to Newington sanitary areas. The 750 deaths referred to measles were more than double the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Kensington, Chelsea, St. Luke, Bethnal Green, Poplar, St. George Southwark, Battersea, Wandsworth, Greenwich, and Woolwich. The 71 fatal cases of scarlet fever were within 10 of the corrected average number; the mortality from this disease showed no marked excess last month in any of the sanitary areas. The 206 deaths from diphtheria were 62 above the corrected average number; among the various sanitary areas this disease was proportionally most fatal in St. Luke, St. George-in-the-East, Mile End Old Town, Limehouse, Bermondsey, Woolwich, and Plumstead. The 580 fatal cases of whooping-cough were as many as 234 above the corrected average number; this disease showed the highest proportional fatality in Kensington, Shoreditch, Bethnal Green, Limehouse, Poplar, Bermondsey, and Wandsworth sanitary areas. The 31 deaths referred to enteric fever were 10 below the corrected average number; there was no marked excess of enteric fever mortality in any of the sanitary areas. The 49 fatal cases of diarrhœa were 23 below the corrected average number. In conclusion, it may be stated that the mortality in London during April from these principal zymotic diseases was more than 65 per cent. above the average.

Infant mortality in London during April, measured by the proportion of deaths under one year of age to births registered, was equal to 136 per 1000. Among the various sanitary areas the lowest rates of infant mortality were recorded in Westminster, Hampstead, St. Martin-in-the-Fields, Rotherhithe, Lambeth, and Plumstead; and the highest rates in Strand, City of London, Bethnal Green, Poplar, St. Saviour Southwark, and Wandsworth.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJORS CHARLTON and Moffitt have arrived in England on completion of a tour of service in India. Surgeon-Major Swabey has been appointed to York, Surgeon-Major Hughes to Brighton, Surgeon-Major Archer to Chester, and Surgeon-Major Cowan to the Cork District. Surgeon-Major Simpson is under orders to proceed to South Africa and Brigade-Surgeon-Lieutenant-Colonel Leake to Bermuda.

INDIA AND THE INDIAN MEDICAL SERVICES.

The services of Surgeon-Lieutenant C. R. Stevens are placed temporarily at the disposal of the Government of Bengal. The services of Surgeon-Captain J. R. Adie are placed temporarily at the disposal of the Government of the Punjab. The services of Surgeon-Lieutenant G. Y. C. Hunter are placed temporarily at the disposal of the Government of the Punjab. The services of Surgeon-Captain C. G. Robson-Scott are placed temporarily at the disposal of the Government of Bengal. The services of the

Digitized by Google

undermentioned officers are placed temporarily at the disposal of the Chief Commissioner of Burma:—Surgeon-Lieutenant C. C. S. Barry, and Surgeon-Lieutenant C. E. Williams. Surgeon-Major J. Anderson is appointed to be Joint Medical Officer of Simla. The services of Surgeon-Major J. A. Cunningham, Civil Surgeon of Simla, are replaced at the disposal of the Government of the Punjab. Surgeon-Captain E. C. Hare is appointed to officiate as Civil Surgeon of the North Lushai Hills, until further orders. Surgeon-Captain H. R. C. Barber, Civil Surgeon, is transferred from Jhelum to Murree. Brigade-Surgeon-Lieutenant-Colonel Francis Cobbam Nicholson and Surgeon-Lieutenant-Colonel Benjamin Evers, Bengal Medical Establishment, Civil Surgeon, Central Provinces, retire from the service subject to Her Majesty's approval.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Surgeon A. M. Page to Royal Marine Depôt, Walmer. Surgeon and Agent: R. Lyddon at Deal.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major Thomas W. Richardson resigns his commission, Surgeon-Captain Casper Robert Laurie, 1st Volunteer Battalion the Duke of Cornwall's Light Infantry, to be Surgeon-Captain.

VOLUNTEER CORPS.

Artillery: 1st Shropshire and Staffordshire: Surgeon-Lieutenant R. P. Mackenzie, M.B., to be Surgeon-Captain. *Engineer: Fortress and Railway Forces, Royal Engineers:* 2nd Gloucestershire (the Bristol): Surgeon-Lieutenant J. M. M. Thomas to be Surgeon-Captain. *Submarine Miners, Royal Engineers:* The Clyde Division: Surgeon-Lieutenant J. H. G. Whiteford, M.B., to be Surgeon-Captain. *Rifle:* 4th (Cambridge University) Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant H. K. Anderson, M.B., resigns his commission. 1st Volunteer Battalion the East Lancashire Regiment: William Moir, M.B., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Duke of Cornwall's Light Infantry: Brigade-Surgeon-Lieutenant-Colonel D. Thomson resigns his commission, also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement, vacating at the same time his appointment in the Plymouth Volunteer Infantry Brigade. 12th Middlesex (Civil Service): Surgeon-Lieutenant T. H. Dickson, M.B., to be Surgeon-Captain. 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: James Allan Wilson, M.D., to be Surgeon-Lieutenant. 6th Volunteer Battalion the Royal Scots (Lothian Regiment): James Cameron, gent., to be Surgeon-Lieutenant. 4th Volunteer Battalion the Hampshire Regiment: Surgeon-Lieutenant G. R. R. Paine resigns his commission, 2nd (Angus) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Lieutenant-Colonel W. F. Murray, M.D., resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement. 2nd Volunteer Battalion the Oxfordshire Light Infantry: Surgeon-Lieutenant C. D. Batt is appointed Second Lieutenant.

DEATHS IN THE SERVICES.

Deputy-Surgeon-General G. Scott Davie, M.D. Edin., Army Medical Staff, at Upper Norwood in his sixty-first year. The deceased officer had a record of long and varied field service. During the Crimean War he served with the Turkish contingent in Turkey and at Kertch. He became assistant-surgeon in the British Army in November, 1858, and surgeon-major in September, 1875. He served as senior medical officer in the operations in Perak, and with the Peshawar Valley Field Force in the Afghan War of 1878–9. In 1882 he served in the Egyptian War and was present at Tel-el-Kebir. In 1885 he was promoted to the rank of brigade-surgeon, and to that of deputy-surgeon-general in May, 1886, when he retired from the service. The late officer, besides receiving medals and clasps with decorations for the foregoing, was also mentioned in despatches for his services. He was a most reliable and valuable officer, of excellent professional attainments, and much respected by all. In addition to his other qualifications he had a good knowledge of the Turkish and Persian languages and had published translations of poetry from the latter.

Surgeon-Major Henry Ogilvy Stuart, on the 11th inst., aged thirty-nine. He was appointed to the Army Medical Staff in February, 1882, and was promoted to the rank of surgeon-major in February, 1884. He served in the Afghan War of 1880 (medal), and was engaged in the expedition to the Soudan in 1884 in command of detachments of the Army Hospital Corps, and was present at the battles of El Teb and Tamai (medal with clasp and the Khedive's star). He was present at the action of Kirbekan, Nile expedition 1884–85 (two clasps).

Surgeon-Lieutenant-Colonel Robert Smith, A.M.S., on the 6th inst. He was appointed a surgeon in September, 1874, and was promoted to be surgeon-major in 1886 and surgeon-lieutenant-colonel in September, 1890. He was engaged in the Boer War of 1881 and in the Soudan expedition of 1885 (medal with clasp and Khedive's star).

ROYAL MILITARY TOURNAMENT.

If the performance may be judged by the promise, the Royal Military Tournament, which will be held at the Agricultural Hall, Islington, from May 28th till June 11th next, should prove one of the best that has yet been organised. Carried out by what is practically a new staff, with Colonel Fox as Military Commandant, it will embrace the leading features of past years, but the committee have infused into the programme new ideas which should make the Tournament for 1896, from a spectacular point of view at any rate, exceedingly popular. In order to give the general public and the world at large some notion of the reserves at the command of the British Empire a grand pageant has been arranged under the title "Sons of the Empire," in which representatives of the home, Indian, and colonial armies will take part. The display of all arms will this year be set in a *mise-en-scène* representing the storming of an Afghan fort. The medical officers in charge of the troops will be Surgeon-Major Alexander of the Coldstream Guards and Surgeon-Lieutenant Kenneth Cameron, A.M.S. During the progress of the tournament a detachment of the Volunteer Medical Staff will appear in the arena, and the St. John Ambulance Brigade will furnish a detachment to attend on the general public in case of need.

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has been graciously pleased to confer the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force:—*North-Eastern District: Rifle:* 1st Volunteer Battalion the Prince of Wales's Own (West Yorkshire Regiment), Surgeon-Major Charles Husband, retired. *North-Western District: Artillery:* 8th Lancashire Volunteer Artillery, Surgeon-Major Arthur Richard Hopper. *Rifle:* 4th Volunteer Battalion the Cheshire Regiment, Brigade-Surgeon-Lieutenant-Colonel William Edward Sevier Burnett; 5th Volunteer Battalion the Cheshire Regiment, Surgeon-Lieutenant-Colonel Patrick Moir Davidson. *Home District: Rifle:* 18th Middlesex Volunteer Corps, Brigade-Surgeon-Lieutenant-Colonel George Danford Phillips Thomas. *Scottish District: Rifle:* 6th Volunteer Battalion the Royal Scots (Lothian Regiment), Surgeon-Lieutenant-Colonel Charles James Allan; 9th Lanarkshire Volunteer Rifle Corps, Surgeon-Lieutenant Edward Henry Kelly.

THE QUEEN'S BIRTHDAY.

The Queen's birthday will be celebrated on Wednesday May 20th next, at all the naval and military stations as well as in London.

Surgeon-Major-General W. Taylor, M.D., was invited by the Queen to Windsor Castle on the 11th inst.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next general meeting of this society will be held at the rooms of the association, 11, Chandos-street, Cavendish-square, on Thursday, May 21st, 1896, under the presidency of Dr. Nicolson. There will be an adjourned discussion on Dr. Hyslop's paper on Pseudo-General Paralysis of the Insane; Dr. Robert Jones will read a short account of Claybury Asylum, the first new asylum of the London County Council; and Dr. Mercier will read a paper on Medical Reticence. The next examination for the Certificate and the Gaskell Prize will take place at Bethlem Hospital in July. Candidates for the Bronze Medal and Prize of Ten Guineas must send in their essays to the President before May 30th, 1896. Particulars of the examination for the Certificate and the Gaskell Prize can be obtained of the registrar, Dr. Spence, Burntwood Asylum, near Lichfield. The members will dine together after the meeting at the Café Royal, Regent-street, at 6.30 P.M.

"Audi alteram partem."

THE CASE OF KINGSBURY v. HART.

To the Editors of THE LANCET.

SIRS,—In your recent issue, dated April 25th, I observe amongst other miscellaneous Manchester news that a society designated a "medical guild" passed in review the judgment on the recently heard case of Kingsbury *v.* Hart and placed on record a pronouncement of dissent from the views expressed by plaintiff's witnesses. As reasons for this dissent are withheld and may come up for review at a later date, perhaps you will allow me to supply mine, seeing that I was one of the witnesses alluded to by the "guild" as testifying on the plaintiff's behalf. 1. In a sense every medical practitioner advertises himself to the public once by fixing a brass plate on his door. 2. Manchester being devoted almost exclusively to business purposes, and dwelling houses being so few in the central parts of the city that they may almost be counted on five fingers, it follows that consulting physicians and surgeons are under a necessity of engaging rooms or offices for professional purposes in the daytime apart from their private residences which are located for the most part in suburban districts and on the gate-posts of which their names and designations are again repeated. We thus arrive at two separate forms of publicity or so-called advertisement, against which no exception is taken, adopted by gentlemen justly accounted honourable, and who act up to the best professional traditions. 3. Another practitioner, following an already existing and commonly adopted custom, has three door-plates at different parts of the town where he follows his calling—one on his dwelling-house and two on gate-posts of hydropathic institutions of which he is the accredited medical referee—stating the hours when he can be seen at each for purposes of consultation. For so doing his fair fame has been libelled and himself stigmatised as one who has grievously derogated from the best traditions of his profession. Failing to realise that this numerical appraisement of brass plates represented, *cæteris paribus*, all the nice gradations between honour and infamy I testified that, in my judgment, Dr. Kingsbury had not laid himself open to the grave imputations brought against him.

I am, Sirs, yours obediently,

Manchester, May 11th, 1896. F. RENAUD.

"THE HISTORY, METHODS, EXPENDITURE, AND POLICY OF THE CIVIL RIGHTS DEFENCE COMMITTEE."

To the Editors of THE LANCET.

SIRS,—Permit me to thank you very warmly for the powerful support you are giving the Civil Rights Defence Committee in the series of articles now appearing in your columns, and especially for that in the last issue—an article, if I may venture to characterise it, dealing with a great subject in a manner worthy of a great journal and placing the position very clearly and definitely before the profession. The work of the Civil Rights Defence Committee will eventually be fully appreciated, not alone by the profession, but by the nation. The cases of Surgeon-Captain Fowler and Mr. Lionel Smith prove how much an organised defence of our rights is needed. Both cases ought to be taken up, and carried to a successful issue not only for the sake of justice, but in the interests of the profession and the public, for the best interests of the public are not served by injustice to medical men, and such oppression and "perversion of justice" are only possible whilst we submit to them. I wish to mention that I have not as a Fellow and Member made application to my College under By-law XV., though fully aware of its meaning and importance; but have, without any such claim, found the College at once, on the invitation of the Civil Rights Defence Committee and on my application, irrespective of the by-law, act in the same spirit as that which prompted the formulation of so admirable a provision—a spirit worthy of emulation by all bodies corporate in their relations to their constituents, whether graduates, Fellows, Members, or Licentiates. It would be difficult to express the comfort I have derived from the moral support of my College under great and prolonged suffering and under the sense of injustice and oppression from quarters whence we are taught to expect only "justice" and "right"; but, however inadequately, I desire to publicly acknowledge it, and I am sure that, as the proper occasion arises, all necessary support will be afforded for the vindication of what you well describe as fundamental rights.

I am, Sirs, your obedient servant,

May 11th, 1896. R. B. ANDERSON.

"THE REGISTRATION OF MIDWIVES."

To the Editors of THE LANCET.

SIRS,—The admirable letter of Dr. Frazer in THE LANCET of May 9th comes as a relief to many of us. The solution of the problem by a Bill based upon the lines set out in it will doubtless be a satisfactory one. These lines, I venture to say, are sound ones, and it is to be hoped that all interested in the subject will combine to produce a Bill which will command united support. The only difficulty I foresee is to be feared from the Midwives' Registration Society, but it is to be hoped that its members will, before it is too late, change an attitude of dictation into one of conciliation.—I am, Sirs, yours truly,

Hatfield, Herts, May 10th, 1896. LOVELL DRAGE.

OXY-CHLOROFORM ANÆSTHESIA.

To the Editors of THE LANCET.

SIRS,—In view of the publicity that the subject-matter of this letter is acquiring it is fitting that you should at least be made acquainted with the fact that in the early months of the year 1891 I first directed special attention to the physiological effects of the inhalation of chloroform. I was led to investigate the matter by the fact that after an experience of some thirty years I continued, in spite of every possible precaution, to meet with cases of "accidental asphyxia," and three successive ones determined me, if possible, to get at the cause of these so-called accidents and to devise a method by which they could be obviated. With your permission I will recapitulate two or three important points connected with the physiology of anæsthesia, and these may be best expressed in the words of the Hyderabad Chloroform Commission: (1) that chloroform has never, under any circumstances whatever, a direct action upon the human heart; (2) that the primary effect of chloroform is to lower the blood pressure, dilate the arterioles, and slow the circulation, both systemic and pulmonary; and (3) that after a certain stage the respiration is slowed, this being in direct proportion to the fall in the blood pressure. Such was the extent of our knowledge when my attention was first directed to the subject, and in stating this I do not profess to have added to our knowledge of the physiology of the process; but accepting the conclusions of the Hyderabad Commission I have arrived at what seems to me to be a rational explanation of the occurrence of asphyxia, and, what is more to the purpose, at a practical and safe method of averting it.

I regard the asphyxia as dependent upon a twofold cause—viz., a lowered blood pressure, with its attendant slowing of the pulmonary and systemic circulation, and a corresponding slowing of the respiration which, interfering with the normal rapidity of aeration, of necessity interferes with the due elimination of the CO_2 of the system. As a result of this slowing of the respiratory and circulatory systems we have by continued inhalation the cumulative effects of an active poison. It was a consideration of this latter fact which led me to devise the method of prevention which I now submit to your notice. It consists simply in the inhalation of a mixture proportionate to the requirements of the case of chloroform vapour and oxygen gas. This by maintaining perfect aeration throughout the whole process ensures regular respiration, consequently escape from the danger attending languid circulation, irregular respiration, and imperfect aeration—viz., asphyxia. Sudden lowering of the blood pressure with pallor the indication of approaching asphyxia, cannot occur because, the nutrition of the heart being unaffected, stagnation in the systemic vessels is prevented by normal activity of circulation. Again, let the required dose of chloroform be what it may, it

Digitized by Google

s impossible to narcotise the respiratory or vaso-motor centres, because, being carried more rapidly to these nerve centres, they succumb the more readily to its influence, less chloroform is necessary, and its action is limited to the suspension of consciousness; recovery, too, is prompt, there being a total absence of the deadly depression which obtains under the old system; and last, but not least, the fortuitous element in chloroform anæsthesia is eliminated to the manifest advantage of all concerned.

A word or two here upon the subject of inhalers may not be out of place. It is, I believe, generally conceded that safety depends, not only upon who gives, but upon the mode of giving, our anæsthetic; but this to be absolutely safe must, whatever the form of the inhaler, be in combination with pure oxygen, regulated and controlled in the manner carried out by Messrs. Arnold and Sons of London.

I am, Sirs, yours truly,

THEO. G. H. NICHOLSON, M.R.C.S. Eng.

Catharine-street, Liverpool, May 8th, 1896.

HORSHAM UNION INFIRMARY.

To the Editors of THE LANCET.

SIRS,—Your strictures on the nursing arrangements at the Horsham Union Infirmary have not surprised me. It fell to my lot to have to visit an inmate in that institution some years ago, when I remarked the unwholesome quality of the bread and butter supplied at the evening meal—the former being of an ash-grey colour and evidently ill-made, while the butter was simply dirty. Though not connected with this union I thought it my duty to call the guardians' attention to the state of the bread-supply; but when my letter was read to the board at their next meeting one of the house visitors resented my remarks and declared that the bread was so good that he should not hesitate to set it before his own family. When the supervision of an infirmary is in such hands one could not expect the nursing and general *ménage* to be of a high order.

I am, Sirs, your faithfully,

Guildford, May 12th, 1896. HENRY TAYLOR.

SANITARY AUTHORITIES AND THE INFECTIOUS DISEASES (NOTIFICATION) ACT.

To the Editors of THE LANCET.

SIRS,—Under the Infectious Diseases (Notification) Act, 1889, has a sanitary authority the power to exclude any disease it thinks proper from the diseases to be notified under Section 6 of that Act? Also, in the case of an outbreak of an infectious disease if two or more persons are attacked in the same house, is it the duty of the medical practitioner in attendance to notify each case separately, and, if so, is he entitled to a fee for each notification? I should be pleased if you would let me have an expression of your views on the above points.

I am, Sirs, yours faithfully,

Dukinfield, May 9th, 1896. E. A. CLARKE.

*** Wherever the Infectious Diseases (Notification) Act has been adopted all the diseases mentioned in Section 6 must, under penalty, be notified by medical practitioners, and no power is given to a sanitary authority to relieve anyone of this obligation under the Act. The same applies to any diseases added either permanently or for a term of years under Section 7 of the Act. Except when otherwise provided for under a special local Act, each case in a house must be separately notified and the same fee has to be paid for each certificate.—ED. L.

THE BARGAIN OF THE RECRUIT.

To the Editors of THE LANCET.

SIRS,—Your Special War Correspondent's article in THE LANCET of May 2nd on the troops in health, their feeding, &c., has interested me much, and I am certain will also be of interest to all who have the welfare of Tommy Atkins at heart. Do we ever consider what sort of a bargain the soldier makes with his country when he enlists? Do we remember sufficiently what he brings into the contract?

A military life may possess its attractions but it also has its drawbacks, and anyone entering upon it must be prepared to sacrifice a great deal. To a soldier, especially when called upon to go abroad or join a campaign, home ties and domestic attractions must be, at any rate for a time, buried luxuries. His tenure of office is uncertain, his employment exceedingly precarious, and his remuneration quite out of proportion to the discomforts experienced and the risk he runs. True he can point to the prospects of a pension in his old age; but how many ever reach such a long-wished-for, well-worked-for goal? A return recently asked for in the House of Commons, if supplied, might possibly answer this very momentous question for us. I believe the number to be very small. Any individual joining the service gives the best and most active part of his life to it, and be he either a short- or long-service man, when he quits the army or navy in quest of employment, having borne, perhaps, for years a character for honesty, sobriety, and application, how often is he successful in securing a situation for which such an exemplary life is so admirably qualified to fill?

He must be possessed of a thoroughly sound mental as well as physical organisation on joining the service, and how often one, or maybe both, of these qualifications are impaired or even destroyed by the foreign service he is called upon to undertake. Surely, then, it behoves our Government to take good care of this excellent material when they get hold of it: to ascertain that the very best of food, drink, clothing, and healthy instruction and amusement be supplied the soldiers; and when sick or wounded to have them carefully attended to and nursed by the best professional services at their disposal. And last, but by no means least, Government should do something to prevent these old fellows—heroes of many fights—finding a cheerless and probably heartless reception in the workhouses or even worse asylums of the rich country for which they have worked and bled. How this is to be done certainly is a problem that remains to be solved, but one nevertheless capable of solution if the momentous question be grappled with by our Parliament in a way it ought to be—and that, too, without delay if the State desires to escape handsomely from an ever-increasing anxiety, and one moreover which confronts its members at every step. Just consider what each recruit brings in as his share of what may be justly termed "invested capital"; what physical and mental qualifications are demanded of the novice before he can expect to satisfy the requirements of the military medical officer who examines him. And let me here remark that even when he has successfully passed his medical examination the applicant may be rejected ultimately on other grounds, for although medical officers in approving recruits have to conduct their examination and record facts arrived at with due care and to the best of their judgment, they are never held responsible for the ultimate rejection of the man on grounds involving a decision contrary to the opinions they may have expressed. On presenting himself for approval the would-be soldier must first of all prove that he is sufficiently intelligent. I presume by this requirement it is merely desired that he should be able to read and write fairly, understand something of figures, as well as exhibit an ordinary amount of intelligence regarding persons and things generally. Then his power of sight is tested and very carefully inquired into, letters and numbers corresponding to Snellin's optotype (test-types for the determination of acuteness of vision) being used for testing the eyesight of each candidate. He is required to pass types numbered D = 6 at 6 metres, or 20 ft. away, each eye being separately tested for that distance. Should the candidate be unable to read with each eye separately and without the aid of glasses Snellin's type marked D = 36 at a distance of 20 ft.—i.e., if he does not possess one-sixth of Snellin's standard of normal acuteness of vision—although he may be able to read types D = 06 at some distance with each eye—he will be rejected as unfit for service. And, finally, he must in nowise be colour-blind. His weight must be normal according to standard. His ears are then examined in order to ascertain there is no defect as far as they are concerned. His speech must be clear and devoid of impediment. The glands of his body undergo an examination in order to ascertain if there exists any enlargement of them anywhere or any marks of a tuberculous tendency apparent. He must be at least 5 ft. 4 in. in height, and his chest measurement not less than 34 in. in circumference.

Digitized by Google

Moreover, it should be well formed and fully developed, a maximum expansion of about 2 in. to 2½ in. being admitted. His heart and lungs must be normal and quite sound. He must not be ruptured. His limbs must be well formed and quite fully developed, with freedom and good movement in all his joints. Even his toes, feet, and hands are to exhibit perfect formation, and, lastly, he must not exhibit any congenital malformation or traces of any previous acute or chronic disease.

It will be admitted that the recruit brings a good deal on his side into the bargain. It is to my mind a question whether he takes enough out.

I am, Sirs, yours faithfully,

May 4th, 1896. DANIEL DEEVER.

"CHARITY BEGINS AT HOME."

To the Editors of THE LANCET.

SIRS,—I have just been filling up my voting-paper for the Royal Medical Benevolent College and am grieved with the thought that there are thirty candidates for pensions and forty-four for the school, of whom only five and nine respectively can be successful this year. Among the candidates for the school are two cases of boys made orphans by the sudden and violent deaths of medical men in the actual discharge of their duties, and of many others where death has followed directly upon professional avocations. Is it not wonderful that men are still found to embark in practice and matrimony without making any provision for their families by insurance of some sort? Allow me to urge upon the young men who at this time of year are just gaining their diplomas in large numbers that they should at once, and while residing in London, join the Society for the Relief of the Widows and Orphans of Medical Men, 11, Chandos-street, Cavendish-square, where, for a single payment of £20 or an annual subscription of two guineas for twenty-five years, they may at least secure that their belongings shall not be left "absolutely unprovided for." Is it not pitiful to find the widows of well-known and respected London practitioners actually begging for bread because their husbands never took thought for to-morrow in the way suggested?

I am, Sirs, yours obediently,

May 9th, 1896. A VICE-PRESIDENT.

THE ARMY MEDICAL STAFF.

To the Editors of THE LANCET.

SIRS,—In reference to the third paragraph of "Brigade-Surgeon's" letter in your last issue, "the abuse," "the endeavour to degrade," and "to make its members ashamed," &c. I joined the service over forty years ago, and at that time and for some years subsequently "the doctor" was, in nine cases out of ten, one of the most popular members of the mess. He was not A.M.S.; he was a regimental officer, and the question of combatant or non-combant was never raised. To us youngsters he was the mentor and friend—especially the friend—not for professional reasons, as may be suggested, but in all matters where disinterested advice and counsel were required; and he had the ear of the commanding officer, and that was often the channel of putting many small crooked things straight without having recourse to official ways and paths. This was the type of those days, though there were, of course, exceptions.

Yours faithfully,

May 13th, 1896. AN OLD SUBALTERN, XLIV.

"JENNER AND HIS WORK."

To the Editors of THE LANCET.

SIRS,—At the present time, when Jenner's merits in relation to vaccination are exciting so much interest, it may not be altogether inappropriate to refer to some of the views of Sir John Simon who forty years ago, when medical adviser to the General Board of Health, gave such deep attention to the subject and embodied in his letter to the President the digested outcome of opinions solicited by him from the most prominent medical men of that time. It may be remembered that forty years ago no memorial was in existence to the immortal name of Jenner, and Sir John concludes his summary of the feelings of the medical world in these words: "Looking, then, to the whole succession of answers and describing in few words what to myself has been the effect of perusing them I would say that, above all, I am struck with their concord. Two hundred and thirty years have elapsed since Harvey first taught the circulation of the blood: the first announcement of Jenner's discovery was but within the adult memory of men who are still living, yet questions addressed to the Governments of Europe and to 542 professors and practitioners of medicine with respect to the older truth, basis though it has long become of all physiological teaching, could hardly elicit more unanimous replies than those which recall the triumphant successes of vaccination. It can be no common certainty which commands so general an assent. It can have been neither a truthless nor a barren doctrine which, within sixty years from its rise, has all but universally satisfied private judgment and has converted nations to be its grateful followers.

"No truth can be thought of against which some one does not rail. And it would be idle to hope, under existing conditions of the human mind, that vaccination should be much more generally credited than it is. Perhaps in no age of the world, proportionately to its instruction, have persons been readier than now to accept physical marvels, and to modify their conception of natural laws at the cajoling of quacks and conjurors. It goes with this credulity to be incredulous of proven truth. Alike in rejecting what is known, and in believing what is preposterous, the rights of private foolishness assert themselves. It is but the same impotence of judgment which shrinks from embracing what is real and lavishes itself upon clouds of fiction. To some extent, therefore, it may be felt a weary and unprofitable work to have spent time and labour in reasserting proofs which, fifty years ago, were exhaustive of their subject; and many eminent men who have favoured me with their assistance may grudge to have given it against superannuated error. Yet if, in final acknowledgment of this assistance, I may be permitted to express what—far better than any thanks of mine—may requite those respected contributors for the trouble they have incurred I would say that they have given to Jenner the monument which, beyond any other, he would have prized. They have made it easy to estimate the full measure of gratitude which is due to the discoverer of vaccination. They have displayed as actual experience what it formally must have seemed mere enthusiasm to foretell. You will read it in the skilled evidence of individuals who, solely with the resources of Jenner's antidote, are maintaining day by day against the most dreadful of infections the victory which he commenced; you will read it in the colossal statistics of nations which, till sixty years ago, were still decimated by that one messenger of death.

"If utility to human life be any test of what is noble in labour, if our teachers of inductive philosophy have rightly advised us—*non tantum veritatè et ordini, rerum etiam usui et commodis hominum consulere*—then assuredly the discovery of which those things are told may rank with any achievement of man. 'Let men rejoice that there has shone so great a splendour from amid their race' is the bidding which, at Newton's tomb, reminds us of our immortal debt to the greatest interpreter of nature and claims kindred for us with the power of his intellect, passionless and 'almost divine.' If corresponding honour be due to the beneficent applications of science, if our immortal state owes love to those who have lessened its weakness and its misery, surely in Jenner has been a second student of nature, who, matchless as Newton in career, might have claimed to lie beside that monarch of the intellect in his last repose and to share the inadequate homage of that grateful epitaph. For though a different it is an equal praise which the members of Jenner's profession vindicate for his honoured name. He too interpreted nature; but, above all, he rendered her teaching fruitful to arm mankind against the worst of pestilences, to widen by his one discovery the horizon of human life, to banish a cruel terror from every mother's heart—such were Jenner's aspirations in his study of nature, such have been the fruits of his philosophy. Members of his profession esteem it their noblest vocation to imitate the endeavours which led him to this transcendent result; and I believe that they, whose contributions to the following pages I respectfully lay before you, will have felt an almost filial pride in expressing their knowledge of facts which consecrate Jenner's place in history."

I am, Sirs, yours faithfully,

London, W., May 11th, 1896. E. A. B.

THE BATTLE OF THE CLUBS.—XXX.[1]

(*Continued from p. 1314.*)

LINCOLN: A MEDICAL PROTECTION FUND STARTED.

WE have received the following communication from Dr. Carline, which we gladly publish. His letter tells very succinctly and clearly the way in which the medical profession has been exploited in Lincoln, and confirms fully our Special Commissioner's report. We wish the New Provident Association every good fortune. The complete success that has attended similar movements when the medical men have determined to help the poor in their own fashion and consistently with their own dignity, and not at the beck and call of lay wire-pullers, encourages us to believe that the disinterested action of the three gentlemen who, for the good of the profession, have refused further connexion with the existing medical aid associations will be duly rewarded. In the meantime we recommend Dr. Carline's letter to the generous attention of our readers.

To the Editors of THE LANCET.

SIRS,—I was requested by a meeting of the medical profession held at Lincoln on the 11th inst. to ask you to kindly insert the following appeal for funds in your next issue.

I am, Sirs, yours truly,

Lincoln, May 12th, 1896. W. A. CARLINE, Hon. Sec.

To the Editors of THE LANCET.

SIRS,—Doubtless the majority of your readers have watched with interest the fight which is in progress in Lincoln. However, when appealing to the profession for assistance a short *résumé* of the facts may be useful. The area worked by the Lincoln medical clubs has a population of 50,000, and of this number some 20,000 obtain their medical attendance through the clubs at reduced rates. The clubs have amalgamated and formed two large institutions managed by lay committees. The resident medical officers, though debarred from private practice, do not receive the whole of the money earned by their exertions. All classes are invited to join these institutions, hence the medical officers have to attend wealthy tradesmen and others in a large way of business as well as those who have retired in affluence. All the abuses of the club system are here in their worst forms. The medical officers of these institutions, having felt that under these circumstances their continuance in office was not in accordance with the usual standard of professional ethics, approached the Lincoln Medical Society with a view to combined action for the remedying of these abuses, and as a result the clubs were asked to establish a wage limit and make sundry other alterations. The committees, however, which are chiefly composed of the interested members, have refused to consider the proposals, and consequently three of the medical officers have resigned and the private practitioners of Lincoln have pledged themselves unanimously to refuse to meet in consultation any persons who may be induced to fill the vacancies. To prevent any injustice to the working-man a provident medical association is being formed which will be chiefly under medical management and will be free from the abuses of the present institutions. In the meantime the lot of the three medical officers who have resigned is a hard one. They have no private practice to fall back on, and yet in the interests of the profession they have thrown up their appointments, thus cutting off their only source of income. Such disinterested action throws a responsibility on their professional brethren, and to meet this the "Lincoln Medical Protection Fund" has been started. The Lincoln medical practitioners confidently appeal to the profession to help them and show their appreciation of the generous way in which these gentlemen have considered the general good rather than their own personal profit. It should be stated that the fund will help to maintain these gentlemen in the New Provident Association until this pays its way, the success of which would mean victory for the profession, and a victory in this stronghold of the club system will immensely help the cause elsewhere. Subscriptions will be thankfully received and acknowledged by the honorary treasurer, Dr. W. A. Carline, Lincoln. Signed by request of a meeting of the Lincoln practitioners. GEO. MITCHINSON, Chairman.

BENEFIT SOCIETIES AND MEDICAL MEN.

A conference was held at the Town-hall, Trowbridge, on May 2nd between representatives of sick benefit societies and medical men in response to a circular issued by Mr. C. E. S. Flemming, M.R.C.S. Eng., L.R.C.P. Lond., of Freshford, near Bath, setting forth that "it is the opinion of medical men that there is an abuse of friendly societies, whereby persons obtain medical aid who are not in a position to need it, which not only affects the various medical officers, but is in many and important respects harmful to the societies themselves. Lord Edmond Fitzmaurice presided, and the medical aspect of the case was described by Mr. C. E. S. Flemming and Mr. A. W. Dalby, L.R.C.P. Edin., of Frome. Medical men from Trowbridge, Bradford-on-Avon, Calne, Devizes, Warminster, Frome, and Freshford were present, and also delegates representing the principal friendly societies in West Wiltshire and the Frome district of Somerset. Mr. Flemming said that club practice was not sufficiently remunerative to enable a medical man to live; he must have a certain proportion of private patients, and if he found these private patients becoming club patients it was only natural that he should complain. No medical man, however, objected to attend a *bonâ-fide* working man as a club patient. A long discussion followed. Many of the delegates held that the medical man had a grievance, but considerable opposition was shown by them to a suggestion that those who are in receipt of £2 per week wages or who live in a house of the rateable value of £15 per annum should not be taken as club patients, and they stated that circumstances in these respects varied in each district. The following was ultimately agreed to with a few dissentients: "That the medical men at this meeting have suggested that £2 per week wages and £15 per year rateable value be adopted as the limit to prevent persons obtaining medical aid from friendly societies who by position do not require it, and that it be recommended by this meeting to the various friendly societies to consider whether any, and if so what, limit can be imposed upon the membership of friendly societies so as to accomplish the above objects."

MEDICAL UNION AT NOTTINGHAM.

On Wednesday, May 6th, the second meeting of this union was held. It was announced that a large proportion of local medical men had already joined the union, while others had expressed their intention of doing so. The meeting proceeded to elect a president, treasurer, and two secretaries, and a council consisting of fourteen representatives of the town with ten of the adjoining district. The council was instructed to at once consider measures to combat the abuses of medical aid and life assurance societies. The meeting was very well attended and throughout harmonious.

THE ASHANTI EXPEDITION.

(BY OUR SPECIAL WAR CORRESPONDENT.)

V.[1]

The Troops in Sickness.

I WILL now give details relating to our troops in sickness as far as the recent campaign to Ashanti is concerned, and in doing so will endeavour to show how varied have been the symptoms, not only in intensity, but also in duration, which

Digitized by Google

have preceded an accession of this African remittent fever, which has placed *hors de combat* nearly one half the troops employed, besides directly or indirectly being the proximate cause of death of seventeen officers and men. From first to last there was little uniformity in the character of the more prominent symptoms or in the way they would attack their victim. One patient, for instance, might complain of simple malaise, think and tell you he had an attack of indigestion, lie down for a short time, and in a few hours be found with a temperature of from 101° to 104° F. Another would perhaps at meal time, especially during the evening, complain of feeling cold and call for his overcoat, and in less than six hours be prostrated with the fever. A third whilst marching would suddenly be seized with a violent headache accompanied with an inclination to vomit, and be compelled to take to his hammock; while a fourth would experience a peculiar feeling along his spine, attended with a feeling of coldness generally, weakness speedily supervening, compelling him at once to seek for medical assistance. In some giddiness and in others lassitude was the first noticeable approach of the complaint. But in the majority of those complaining, if they were destined to go through a lengthened course of the fever a peculiar heavy look of the eyes was very noticeable, and more so if these were suffused, the pupils of the eyes performing their motions very languidly. The seizures in some cases were extremely sudden as well as unexpected—in my own case markedly so. Although I had served on the West Coast of Africa before, as well as been some years in the West Indies and passed through two epidemics of yellow fever, I never suffered from malarial fever until my recent visit to Ashanti. I neither considered myself, as far as constitution went, predisposed to, nor was I in any way afraid of, it, yet I had a severe attack this time for all that. On the day of its accession I had risen after a comfortable night's rest about 4.30 A.M., feeling as well as I had ever done in my life. The majority of the marches were completed and we were gradually nearing King Prempeh's stronghold, and most of us were in high spirits, expecting an easy capture of his place and a speedy return of the troops to the coast line. The Special Service Column was timed to leave Kwissa about 6 A.M. I had arranged to strike my tent early and journey forward on foot with them. My head man overslept himself and, of course, the hammock-bearers followed suit, so that I had to march on that morning without my usual cup of coffee; in fact (what I should condemn in anyone else), I commenced work on an empty stomach. Not only so, but having gone up to camp to learn how Prince Henry of Battenberg was (having ascertained from the Principal Medical Officer the previous evening that he was somewhat indisposed), I was terribly shocked to find that the poor fellow was down with remittent fever and had to be sent back to the *Coromandel* as soon as possible. I had already been considerably irritated by the procrastinating conduct of my Fantee men, added to this the painful intelligence respecting Prince Henry of Battenberg's seizure came as an unexpected blow to further distress and unnerve me. When we looked upon the wan countenance of one of the noblest, bravest, and most lovable of men I ever met with in my life — we all sympathised deeply with him in his misfortunes and truly felt a degree of sorrow that words fail to describe for the dire calamity which had so unexpectedly and so mercilessly overtaken him. Still, everybody encouraged him to hope for the best, and solaced him with the assurance that his enforced "going down" would only be of a temporary character (they had then no reason to think otherwise), and that he, with his bright, cheerful smile, would at no very distant date be taking his part in our midst again. Alas for human judgment. The unexpected often happens and the best prognosis sometimes fails. Daylight was dawning, the various companies with their officers were ready for a start, and clearly rang out in the chilly morning air the command, "Battalion, attention!" "Right!" "By your left, quick march!" Away went those fine fellows of the Special Service Column, stepping out as fresh and fit as if they had just come out of Aldershot. Even then my carriers were not ready, and I had, in order to overtake the rear-guard, to do a little running on my own account, leaving my lazy blacks to follow me at their own jog-trot pace.

This exertion to a certain extent overheated but certainly did not in any way distress me. Having been an amateur cricketer all my life I enjoy a fair amount of active exercise, and it never tells upon me in a way it might upon others of a similar age to my own. To proceed, however; I came up with Canon Taylor Smith and a military medical officer about half a mile out from Kwissa, and we three were footing it together in the rear of the column, which was marching at a rattling pace towards our destination. Several miles had been covered, and our next station had nearly been reached when quite suddenly I became aware of a sharp pain shooting across my temples, succeeded by a sort of feeling of constriction, as if a string had been tightly tied round my cranium. Thinking that my white helmet, which I was then wearing instead of my ordinary sombrero hat, was possibly the cause of the inconvenience I removed it and carried it under my arm (as the chaplain was also doing), but to no purpose, for, as far as any relief was experienced, I had scarcely gone a dozen yards before I came to a dead halt. All movement in the muscles of my legs ceased, my inferior extremities refused to carry my body an inch further. Moreover, a severe griping pain was experienced at the same time across the pit of my stomach, succeeded by a deadly feeling of coldness creeping over my whole body, my fingers presenting an appearance of lividity. It was some time before my bearers arrived, and when they came up and had lowered my hammock it was with the utmost difficulty that I could manage to get into it.

A few minutes afterwards the Special Service Column was halted and the military medical officer, with the kind approval of the officer commanding, quickly passed me on through the lines to the next village so that my case might receive the attention it required. The time from the first intimation of seizure to perfect helplessness scarcely exceeded a period of five minutes. Prostration was rapid and complete. Added to this I felt terribly cold, with an inclination to vomit, and as the head-quarter staff had not as yet come up I suggested that Mr. Bennet Burleigh should kindly give me forty drops of chlorodyne from a bottle I then had in my travelling case. This dose had the immediate effect of making me vomit a considerable quantity of bilious matter and afterwards of warming me thoroughly and sending me into a pleasant sleep. As soon as Brigade-Surgeon-Lieutenant-Colonel Taylor saw me he promptly pronounced my case to be one of fever and treated me accordingly, and to his kindness and unremitting attention I feel convinced I am indebted for the preservation of my life. Before noticing the more prominent symptoms that accompany remittent fever throughout its successive stages I may here observe that, as far as I was personally concerned, I experienced no pain whatever after the initiatory symptoms had passed off. I felt no thirst during the whole period of my illness, but the sense of taste was completely lost and a desire for food of any kind quite gone. As long as I remained in a recumbent position no serious inconvenience was felt, but directly I attempted to move the pulse appeared to quicken and the superficial arteries of the head to throb with an increased impetus so as to be inconveniently felt when the side of the head was resting on the pillow. In my own case the exacerbations of fever returned with unswerving punctuality every evening about seven o'clock. The paroxysms of distress increased in intensity towards midnight. I lay awake for several hours until that apex of discomfort had been reached, and when the fever symptoms were diminishing in force fell asleep, only to have that brief period of slumber again and again broken by the most hideous and fantastic dreams.

The first case of fever that came under my observation happened at Mansu. The man, a sapper belonging to the advance company of the Royal Engineers, working with a party laying the telegraph wire, was seized with a feeling of cramp in his stomach about 5 P.M. and brought back to camp at the rest station about 8 P.M. the same evening. On arrival he was cold and collapsed, with a quick, thready pulse, foul tongue, and a temperature of 101·7° F. A stimulant was immediately given to him, and he was wrapped in blankets, and put to bed. In the morning he described himself as "feeling much better." As his bowels were confined a slight aperient was administered, followed by three-grain doses of quinine every four hours. The purgative had the desired effect, and the quinine reduced the fever appreciably. He returned to duty three or four days afterwards only to be again placed on the sick-list a week or so later with a less aggravated attack.

In noticing the peculiar character, duration, and course of the attendant symptoms in this and other cases which have

Boat conveying Prince Henry of Battenberg to H.M.S. *Blonde*.

Digitized by Google

come under my observation I must say I have never noticed any marked shivering at the onset, although prior to the vascular excitement the patient complains of great coldness, sometimes in his stomach, but more often in his limbs, particularly at the extremities of his fingers and toes. This coldness is sooner or latter followed by excruciating headache or a sense of giddiness, intense heat of the skin, restlessness, vomiting, or rather nausea, and dyspnœa. Some experience great thirst, others, strange to say (as in my own case), none at all. In from two to four days the tongue, although moist to the feel, becomes covered with a whitey-brown fur over its top except just at the edge, which remains of a bright-red colour and seems indented at its extremity. The countenance in some is flushed, in others pallid, but the conjunctiva is nearly always suffused, whilst the eyes have a wild, almost maniacal, look about them. The temperature at the onset is generally found to be three or four degrees above normal and varies considerably daily during the continuance of the fever. In the more serious cases the temperature often touches 105·55° or 106° F. without a fatal result to the patient, and I know of one officer whose temperature was at one time as high as 108° F. and yet he pulled through and is still alive, so far as I am aware, to substantiate the fact. In the majority of cases there was considerable tenderness over the epigastric region, whilst the urine at the onset was passed in a diminished quantity and, moreover, in a highly coloured state. During the abatement of the fever the urine is voided less frequently and in increased quantity, and as convalescence is approached it gradually regains its proper hue. The pulse is rapid and small, sometimes very compressible, and seems influenced to a considerable extent by the slightest movement or even noise. In a few cases—not all—a most peculiar fetid odour was noticeable, especially so in strong, robust subjects, in whom perspiration was free and profuse. The smell certainly was not that observed in severe rheumatic cases, but was quite as pungent as well as far more disagreeable to those in attendance.

Some patients on seeking medical advice complained of considerable pain along the spine at the onset of the fever. A subsidence of febrile action in general followed in from four to seven or eight hours, or, at all events, the symptoms if continued beyond the latter period became much mitigated. Diaphoresis came on, the thirst moderated, and the signs of oppression in a great measure disappeared. The perspiration that was a prominent symptom of the complaint continued during the whole of the paroxysm, and after it had passed off the patient appeared considerably relieved, the question "how he felt" in nine cases out of ten eliciting the reply that "he felt quite well." This, however, was more apparent than real, for in a few hours the sufferer was as bad as ever. Sometimes a respite would be extended to some four-and-twenty hours, possibly to even as many as eight-and-forty, but in such cases the fever frequently returned in an aggravated form, as if the febrile action had only rested to return with renewed force. These renewals of exacerbations, moreover, seemed to observe no definite form of periodicity. They would return in some cases at dawn or in others at midday, but in the majority were more frequent in the evening. Under such conditions it can be well understood there was always a difficulty in deciding which were critical days and which were not, but there is little doubt that if no improvement (I mean a complete lessening of the more urgent symptoms) was visible by the end of some ten days the case would turn out to be a very serious one. Moreover, if the urine, instead of increasing in volume with a diminution of colour taking place, presented exactly opposite conditions then uræmic poisoning would probably follow, and "black water" fever, as it is called, had assuredly set in.

On my visiting Prahsu Hospital on Jan. 17th, 1896, I learnt the following particulars from Surgeon-Lieutenant-Colonel Blennerhassett, A.M.S., who kindly placed all records at my disposal. Since Dec. 24th, 1895, the admissions into his hospital were as follows. White officers, 6; privates, 47; coloured officers, 0; coloured troops, 30; general total admissions, 6 officers and 77 men, or 83 all told. The majority of these cases were due to remittent fever, the temperature varying from 100° to 109° F. The latter temperature was reached in the case of the late Major Fergusson, of the Royal Horse Guards, and during his treatment in hospital this very high state of fever was only reduced by wet packing and cold sponging to 104°. The death of this much lamented officer occurred within a few days of his first observable symptom and was due to hyperpyrexia with suppression of urine, accompanied by a hot, pungent, dry skin, which all treatment failed to restore to its normal condition. His decease was as sudden as it was unexpected by those who knew him and loved him so well. He lies buried in Prahsu Cemetery beside another officer who died at this place during a former expedition (*vide* Fig. 1), the small wooden cross denoting the spot where he is interred. Nearly all the officers who resided for any time at Prahsu had an attack of fever. The next highest temperature which was recorded was 105·4°, which occurred in the case of a private in the West India Regiment, and close on his heels followed a company sergeant-major, also of the West India troops, whose temperature reached 105°. A sapper's highest was 104°. The remaining cases varied from 103° to 104°. At one time three out of four medical men were down with this complaint at Prahsu. I have been given to understand that in the matter of medicinal remedies calomel, quinine, antifebrin, and phenacetin, in their order of sequence, proved the most useful in subduing this malarial scourge. Surgeon-Lieutenant-Colonel Blennerhassett says that calomel in moderate doses, followed by magnesium sulphate, proved of great service in clearing the way for the administration of quinine and the other remedies. Prognosis must always be rather gloomy in the cases of sufferers from this kind of fever when a decided improvement is not evident by the end of the tenth day. By this time they generally become irritable, weak, and exhausted, any decided remissions being most indistinctly marked. Moreover, the skin remains dry, the tongue, losing its moist character, appears parched, and the pulse small, feeble, and irregular—in fact, the complaint has then assumed a low and distinctly typhoid character. Notwithstanding this, the patients may again and again, on account of the entire absence of any pain, express themselves as feeling "quite well." When the fever takes a favourable turn the remissions become more and more distinctly marked and the intervals considerably extended. The countenance assumes, too, a far more natural expression. The heat of the skin lessens, thirst is diminished, the pulse becomes fuller and less rapid, whilst the tongue gradually loses its fur and to the touch feels more moist. Diarrhœa often at this time sets in, but generally disappears after four or five motions have been passed, and, with care and good nursing, convalescence is speedily established; but exceeding carefulness must always be exercised during this period of convalescence. Patients improve considerably on removal from the coast to a healthier climate, for instance, seaward or to England, but the transition must not be too abrupt, for it is a well-known fact that these fever cases doing remarkably well for some days on the homeward voyage often suffer severe, even fatal, relapses as soon as they reach the cooler latitudes of the North-east Trades, and many having entirely lost the fever during the trip have experienced quite a serious relapse on their arrival on British shores.

Considering that I was laid by with fever only two or three hours after the late Prince Henry of Battenberg was carried back to the coast I am quite unable to record the subsequent history of his case; but from all I have since learned from those well-qualified to speak he received the best professional attendance and nursing that it was possible to give him. I followed him down to Cape Coast Castle as an invalid by the admirably arranged hospital train, only in time, however, to find he was just being removed to the vessel that was prepared to take him home. Fig. 2 shows the native-manned boat conveying His Royal Highness to H.M.S. *Blonde*, the vessel on board of which he unfortunately died.

INAUGURATION OF THE HAARLEM CHALYBEATE BATHS AND SPRINGS.

(FROM A SPECIAL CORRESPONDENT.)

A NEW health resort has just been inaugurated within easy access of London, the Midlands, Yorkshire, and Lancashire. Valuable mineral waters have been discovered near the old, interesting, and historical Dutch town of Haarlem. Like many other valuable things the discovery was the result of a pure accident. Some fifty years ago attempts were made to drain the Haarlem Mere—a vast sheet of

Digitized by Google

allow water covering some 40,000 acres of land. It was rrectly thought that the land would be valuable for ricultural purposes if it could be reclaimed, and at its drainage would also contribute to render e town more healthy, for the inhabitants occaonally suffered from intermittent fever. Dykes were ilt, canals constructed, and windmills erected to mp out the water. The windmills, however, were not werful enough to effect this end and steam pumps great strength were obtained from England. At last tch perseverance got the better of all the difficulties, the ere was drained, and the whole of the reclaimed land put der cultivation. The rich, peaty soil amply repaid the bour that had been expended. Valuable pasture land was eated in some portions of the mere and good crops were own in other parts. At present one of the favourite plants ltivated is the caraway, which produces the aromatic ed which is used in the manufacture of the well-known queur called Kümmel. Several farmhouses were conructed on the mere, and wells had to be dug to satisfy the ants of the inhabitants. To obtain drinkable water it was cessary to dig to a great depth, ninety or more feet, and e wells were all on the Norton principle. When the good ater had been reached an iron pipe was inserted. The water en rises up the iron pipe, which protects it from mixing ith the water in the higher levels. After some time it as noticed that the cattle that drank the water of e of these wells prospered in so marked a degree at the farmers concluded the water possessed special alities. A gentleman having noticed that the ditches in hich this water flowed were very much stained by iron posits took some of the water to Mr. Loomeyer, a local emist, who in his turn brought it to the notice of several edical men. Samples were then sent to Professor Gunning, emonstrator of Chemistry at the Amsterdam University. ere the water was again analysed. Then a theoretical scussion arose as to the origin of the spring. Did it come om Germany? Was it an offshoot of the celebrated rmont chalybeate springs? This hypothesis was gradually andoned in favour of the conjecture that it was what ight be described as a local mixture. Haarlem is near the a and all along the shore there is a range of low sand owns which act as a sea wall. The rain which falls on these owns forms a layer of fresh water at but a few feet below e surface of the sand, which, however, communicates with e sea-water that is found at a lower level. The fresh ater comes in contact with the iron in the soil and dissolves out as a ferrous salt. Thus, in this water, as in the issengen waters, there is some ammonium chloride present, hich, it is urged, must be derived from the sea water and is ot due to any form of contamination. In any case the proortion of ammonium chloride is stated to be less than that oticed in the Kissengen waters. Nevertheless, this makes imperative that the construction of the well should be such to defy any possibility of contamination. Throughout the hole of this province there is a salt-water layer at about feet to 120 feet below the surface. Two years ago experients were made and a well was sunk to a very great depth ar Haarlem; but the deeper the well the more salt became e water, and with salt water there is always a little mmonium chloride. Ten metres below the surface there is nerally a layer of alluvia, and it is supposed that at some metres to 40 metres the fresh water, which, bearing also me phosphates, has dissolved the oxides of iron into ferrous lts, meets some of the salt water, and hence is found a ineral water containing an unusually high proportion of loride of sodium.

Whatever may be the value of these theories the analysis ints to the discovery of a valuable spring. Professor ockvis had indicated in his remarkable theoretical works this subject what should be the constituents of a chalyate water, and when subsequently the waters from the aarlem Mere were submitted to him he recognised that ey contained what he had theoretically held to be the siderata. Professor Stokvis writes: "I do not hesitate to alify this water as an excellent ferruginous water, which ay unquestionably be ranked amongst other known rruginous springs; nay, in some respects it surpasses em. This the chemical analysis proves so convincingly at any special recommendation of this chalybeate water ems almost superfluous." Thus encouraged, several gentlen living at Haarlem pushed the inquiry still further. Some the water was put in bottles and sent to a large number of edical men in different parts of Holland with the request that they would give it a trial. Seven years ago a sort of congress or meeting was held to which these same medical men were invited. Several attended and compared their notes. The result was most encouraging. Professor Huet of Leyden, notably, compared the water with that of Pyrmont and related the good effect it had produced on his patients. It was then decided to continue to make investigations for another year and to send further samples of the water to medical practitioners. Finally, when, after the lapse of this time, the reports were again found to be, if anything, even more favourable, some of the leading inhabitants of Haarlem determined to try to work the spring commercially. In 1892 a company was formed which proceeded to build a casino at Haarlem, close to the beautiful wood or park of that town.

In view of the approaching season the Wilhelmina Spring Company determined to inaugurate their enterprise by an opening ceremony. A number of English journalists were invited, and on April 12th last, together with seven colleagues of the daily, weekly, and scientific press, I left London at 8.30 P.M. for Harwich. In spite of the rough weather the magnificent new steamers of the Great Eastern Company landed us at the Hook of Holland at five the next morning. By half-past seven we were already at Haarlem. It will be seen, therefore, how easily the journey can be accomplished from London; but it is equally easy to reach Harwich from the midland counties and the north of England. On arriving our first visit was to the bath-house. It consists of a central building, with two low wings on either side, one for ladies and the other for gentlemen. Both sides are similarly constructed. There is, first of all, a waiting-room, then the medical man's consulting-room, communicating with a chamber in which electric baths can be taken, and after this the resting-room for those who have taken their bath. These rooms are so arranged that the medical attendant can, if necessary, render any assistance to the patient. Then there are six ordinary bath-rooms, with glazed hardware baths, hot and cold water douches, &c. Provision has been made for giving chalybeate baths with or without the addition of carbonic acid. Then there are rooms at the back—shut off with double doors so as to keep unpleasant odours from pervading the other parts of the establishment—where sulphur, salt, and mud baths can be given. Douche and jet baths in every possible form have also been provided, and to facilitate the reaction after bathing there is a gymnasium. The whole seems very neat, appropriate, and so constructed as to preserve the utmost cleanliness. In respect, however, to the drainage it may be observed this has not been contrived with sufficient care. At Haarlem the old French heresy, which has so often been denounced in these columns, still prevails. The law does not allow direct drainage into the sewers, but sanctions a system which greatly increases the danger that arises from sewers. Rain water and slop water may drain direct into the sewers, but closets must drain into cesspools. As, however, these are not dry closets, but English wash-out closets with a two-gallon flush, the cesspool is, of course, promptly filled; therefore, permission is given to insert an overflow pipe communicating from the cesspool to the sewer. Under such circumstances it would be much safer to drain directly into the sewer, for then the sewer would only receive fresh sewage, which, if the sewer is properly built and flushed, would be carried away so promptly that it would not have time to ferment and cause mischief. As it is, the sewage goes to a cesspool. The heavy substances sink to the bottom of the cesspool, where they remain for weeks fermenting and polluting to a high degree the water, which, after washing over this foul sewage, is allowed to overflow into the public sewer. It is needless to point out that a cesspool with an overflow does not prevent the contamination of a sewer, but greatly increases that contamination, because it pours into the sewer stale instead of fresh sewage. With sewers thus rendered foul and with a cesspool charged with an accumulation of sewage the precaution of very careful disconnexion between the drains of the bathing establishment and the cesspool and the sewers is more than ever requisite. The water from the baths flows into dip traps situated outside the walls of the baths. But these traps are not ventilated; they are also clumsy contrivances likely to become foul. It is not, however, necessary to enter into a full description of the drainage of the baths, for on my pointing out these defects the directors at once promised that they should be remedied. Indeed, after all the ceremonies and

Digitized by Google

festivities were concluded the directors and the architect showed me the plans of the drainage, and I pointed out what alterations it seemed to me should be made. Orders were then and there given to at once undertake the works to disconnect and to ventilate every drain pipe and provide both inlet and outlet apertures, so that every drain-pipe may be properly ventilated with a current of air throughout the whole of its course and absolutely disconnected from the cesspool and the sewers.

Haarlem, it is well known, is the great centre of the bulb trade, and just at this moment there are acres upon acres of land covered with beautiful hyacinths and tulips. This suggested that Haarlem, like Nice, might have its battle of flowers. Instead of carriages, however, the carnival was conducted on velocipedes and formed part of the programme for the inauguration of the springs. It is scarcely within my province to describe these festivities. That 40,000 excursionists came from Amsterdam alone to witness the procession is, however, a fact which will suffice to show how much the *fête* was appreciated by the public. There were specimens of velocipedes dating back more than 100 years and others of more recent manufacture down to the most modern improvements, all gaily decked with flowers and mounted by riders in fancy costumes. As they passed the crowd marked its approval by showering flowers upon them. It was an animated, joyful, and pretty sight.

On the following day we were taken to the seaside resort of Zandvoort, which is reached by steam tram from Haarlem in about twenty minutes. Thus it is possible to combine treatment at the mineral springs with sea bathing or healthy exercise on the seashore. A beautiful sandy beach stretches for several miles on either side of Zandvoort, where there are numerous hotels and accommodation for visitors at moderate cost. From this place a pleasant drive brought us to Ymuiden, where the sea canal from Amsterdam falls into the North Sea. Here are some of the largest locks in the world, a new fishing port, and generally much to interest tourists.

It was on the third and last day of our visit that we were taken to the Haarlem Mere to see the springs. After a good long drive we reached that portion of the mere where the springs are situated. A shallow circular well receives the water from the Norton pipe, which is in its centre. At first it consisted only of bricks. These, however, have been carefully covered with cement and concrete and the floor of the well has been treated in the same manner. Thus the surface water cannot penetrate the well. But there was great difficulty in ascertaining what was the depth or length of the Norton iron pipe or what was its actual condition. Ultimately, it was ascertained that the man who throughout this district had sunk these Norton wells had always been obliged to go down to a depth of thirty or forty metres, and there was no reason to believe that this well differed in any way from the others in the neighbourhood. Still, it would have been more satisfactory to have had more positive evidence of the fact. Then there is always the danger that, in the course of time, the iron pipe may so corrode as to admit some small quantity of water from higher levels than that at which the chalybeate water is taken. I, therefore, ventured to suggest that soundings should be made, and, if possible, a glass coating or lining should be introduced within the Norton pipe. The directors endorsed this opinion and promised that measures to this effect should at once be taken. Close at hand there is another spring which contains a much smaller quantity of iron and which has a well constructed in the same manner. This is called the Hollandia spring. The water from this well is placed in iron tanks of 4400 litres capacity and air is blown through for an hour. The air oxidises the iron, which, after twenty-four hours' rest, has all sunk to the bottom of the tank. The water is then filtered through animal charcoal, gravel, and sand, and carbonic acid gas is added. It is then bottled and sold as an aerated table water. It seems to be an excellent water for such a purpose, but the analyses of this spring have not yet been published. The Wilhelmina or Chalybeate spring yields about 60,000 litres in the twenty-four hours, and the Hollandia, or table-water spring, about 40,000 litres.

In the afternoon the Mayor of Haarlem officially opened the pump-room near the casino, where the Wilhelmina water is brought to town through iron pipes, and in the evening a final banquet was given in honour of the guests. At this dinner the director of the company, Mr. J. Scholten, in an eloquent speech, alluded to certain criticisms indicated in this article and promised that the suggested improvements should at once be carried into effect, declaring that no pains would be spared to render the baths and springs of Haarlem perfect in every respect.

Haarlem, April 16th, 1896.

[An analysis of the Wilhelmina saline and chalybeate water was made in our laboratory some time ago and the result was published in THE LANCET of Oct. 6th, 1894. The water was found to be charged with carbonic acid gas under slight pressure, and it was observed that the dissolved iron remained intact for some time; that is to say, the iron did not readily separate in the form of hydrated oxide after the manner of most chalybeates containing iron in the ferrous state. This is probably due to the presence of an important quantity of alkaline salts, consisting chiefly of the chlorides of magnesium and sodium, with a distinct amount also of chloride of ammonium. The presence of these salts, as was pointed out, is doubtless an advantage, especially in regard to the otherwise constipating effect of iron and many of its compounds. The genuine character of the water is established by the fact that a brief examination of the spring made by our correspondent on the spot confirmed, so far as it went, the results obtained with a specimen of the bottled water examined in THE LANCET Laboratory more than a year ago.—ED. L.]

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Ladies' Charity and Lying-in Hospital.

A MOST enthusiastic meeting of the local members of the profession, at which over 200 were present, was held on May 11th at the Medical Institution to consider the recent position taken up by the committee of the Ladies' Charity towards its medical staff, which has involved their entire resignation. The following resolutions were moved in an able and appropriate speech by Mr. Mitchell Banks and carried, the first unanimously and the second with but one dissentient (who, by the way, was completely in accord with the general feeling of the meeting, but differed only in the terms of the resolution):—1. "That this meeting of the medical profession view with much indignation the recent action of the board of management of the Ladies' Charity and desires to express its warm approval of the action of the staff in refusing to hold office under the conditions proposed to them." 2. "That this meeting trusts that while the present regulations are in force at the charity, no member of the medical profession will accept office at that institution or will give assistance on or after the 19th inst. to its officials, either gratuitously or for gain, thus rendering the board of management responsible for any dangerous consequences that may occur to patients treated by their officials." The object of the second resolution was to give timely notice to the board of management that after a certain date—viz., the day following that fixed for receiving applications for the vacant posts—they must not expect any assistance from the late staff. It may be mentioned in passing that the attempts made to induce gentlemen to accept office by the offer of pecuniary considerations were, to say the least, undignified, and it is much to the credit of a respected member of the profession that he declined, when asked to do so, a fact most favourably commented on by his brethren. The meeting mentioned above was attended by two lady doctors, who were in thorough accord with their male brethren. The whole business is discreditable, and it is a matter for much regret that the centenary of the charity should be marred by these unhappy disputes, which in a well-regulated charity ought never to have occurred. It is an additional illustration of the unfortunate consequences which may ensue when the medical staff of any hospital is without a single representative on the managing committee.

Post-graduate Course.

The syllabus of the post-graduate course which has just been issued states that the lectures and demonstrations, of which there are thirty, will commence on May 12th and terminate on June 30th. The lectures will be held in the medical school of University College, Liverpool, on Tuesdays and Fridays from 2 P.M. to 3 P.M. The introductory lecture

Digitized by Google

ill be given on May 12th by Professor Patterson, dean of he medical faculty. The demonstrations will also be given n Tuesdays and Fridays; they will be held at the various eneral and special hospitals throughout the city.

Death of Dr. J. M. Packer of Huyton.

It was with much regret that the profession in Liverpool nd Huyton received the intelligence of the death of Dr. . M. Packer, who succumbed on the 1st inst. after a few ays' illness. Dr. Packer was for many years in practice at luyton, where he was highly esteemed by his professional rethren and by his patients, whose confidence he completely njoyed. He was educated at King's College and at St. Mary's lospital, at which latter he was formerly house surgeon. He btained the Membership of the Royal College of Surgeons f England in 1862 and graduated as M.D. at the University f Edinburgh in 1863. He was fifty-eight years of age.

Liverpool Medical Club.

The Liverpool Medical Club, which was recently opened, eld its inaugural dinner at the Adelphi Hotel on the 0th ult., Mr. Mitchell Banks, President of the club, in the hair. It is registered under the Companies Acts, 1862 to 890, whereby the liability of the shareholders is limited to he amount of their shares. It has for its objects the pro- notion of professional unionism and the discussion of thical matters, besides affording the advantages of an rdinary social club. The premises, which are tastefully urnished and supplied with all modern conveniences, are ituated in a central part of the city within easy access of he different railway stations. Dr. Edward Adam is the hairman of the board of directors, the vice-presidents of the lub being Mr. J. E. Burton and Dr. G. G. S. Taylor.

Prosecution under the Glanders and Farcy Act.

Proceedings were taken at the Liverpool police-court on he 29th ult. against a veterinary surgeon for neglecting to otify to the police the existence of glanders in a horse vhich was under treatment in his stables for an injury to one f its legs. At the end of a week it was discovered to be uffering from glanders, and according to the evidence he ept the horse for another week in the same stable with other orses. The prosecution was laid under the Glanders and Farcy Order, 1894, issued by the Board of Agriculture under he Diseases of Animals Act. Persons having charge of an nimal affected with glanders are bound to notify the fact o the police, who then apprise the local authority whose luty it is to order the slaughter of the diseased animal nd its carcase to be buried, covered over with quick-lime, nd with not less than 6 ft. of earth over it. The defendant leaded that it was a doubtful case of glanders as blood- oisoning might have resulted from the kick, and in the arly stages it was difficult to diagnose glanders. He also tated that the horse in question was kept it a loose-box ompletely isolated from other animals on his premises. The ench, however, considered the case proved, and fined the efendant £5 and costs.

A New Parish Hospital for Toxteth-park.

The Toxteth board of guardians are in similar straits with heir brother guardians of the adjoining parish of Liverpool s to the want of accommodation in their workhouse for sick oor. The majority of the guardians at a recent meeting dvocated the building of a new infirmary at a cost of 11,000. It was pointed out that the increase in the number f nurses in recent years was an argument in favour of the roposed extension. It was eventually decided to proceed vith the new building.

West Kirby Convalescent Home.

This convalescent home has been enlarged by the addition f a new wing, which has just been opened. For some time ast the committee have been unable to deal with the umerous applications for admission, and by the generosity f a few friends the funds were provided for erecting the ew wing. It is a handsome red-brick building to match the main block, its chief internal features being the provision of isolation rooms for infectious diseases and a special ward for rippled children. There is also a disinfecting chamber and a large, well-lighted day-room. The building, which has cost £3000, will give accommodation for an additional thirty beds.

May 13th.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Bristol Eye Dispensary.

THE first annual meeting of the Eye Dispensary since its reconstruction was held on April 28th. The report stated that 1667 patients had been treated during the past year, giving an average of thirty-two fresh cases every week, exclusively of those already undergoing treatment. The financial statement showed that there was a balance in hand of £40.

The Wellington (Somerset) Board of Guardians and the Medical Officer to the Workhouse.

Recently the Wellington Board of Guardians twice declined to grant an application by the medical officer of the workhouse for an increase of salary from £30 to £50 per annum. The officer accordingly resigned. Advertisements were issued inviting applications for the post, but at the meeting on May 1st the clerk reported that none had been received. The board had now decided to apply to the Local Government Board for sanction to increase the salary from £30 to £40.

Annual Extra-Collegiate Meeting of the Court of the University of Wales.

The annual extra-collegiate meeting of the Court of the University of Wales took place recently at Cardiff, Mr. Humphrys Owen, M.P., presiding. Dr. Isambard Owen and the chairman were re-elected vice-chancellors. Lord Windsor, in welcoming the court of governors said that Cardiff took an interest no less than any other part of Wales in the valuable educational work in which the University was engaged. The estimate of expenditure for the year ending March 31st, 1897, amounted to £4496, and has been submitted to Her Majesty's Treasury. The Court empowered the standing executive committee to take immediate steps to raise funds for the purpose of the foundation of fellowships and scholarships.

The Water-supply of Bath.

At the meeting, held on April 30th, of the Bath Waterworks Committee it was reported that the reservoir at Monkswood was nearly completed and that at the present time there were 17,000,000 gallons already stored.

Bacteriological Researches in Connexion with Cheesemaking.

The committee of the Bath and West and Southern Counties Society have fitted up, on behalf of the Somerset county council, a cheese school at Cossington, near Bridgwater. A laboratory has been added to this, and Mr. F. J. Lloyd, F.C.S., is conducting, under the direction and at the cost of this society, bacteriological and other researches in connexion with cheesemaking. Mr. Lloyd is anxious to give information and assistance to any farmers who discover any difficulties in the making of Cheddar cheese.

An Infectious Hospital for the Carmarthen Asylum.

At the quarterly meeting of the Pembrokeshire county council held last week the council approved the proposal of the committee of visitors of the Carmarthen Asylum to erect a new detached infectious hospital for eight beds at a cost of £1000 on the building.

Hospital Saturday in Bristol.

It has been definitely decided that June 13th shall be observed in Bristol as Hospital Saturday. In addition to the usual street collections on that date a *fête* will be held at the Zoological Gardens, Clifton, when an ambulance corps will give demonstrations and several entertainments will be provided. The charities to be assisted are the Royal Infirmary, General Hospital, Children's Hospital, Eye Hospital and Dispensary. It is stated that Bristol has to maintain five principal medical charities at a total cost of over £30,000 per annum; that the city has a population of 225,000, of whom about 3500 are regular subscribers, and the contributions in subscriptions do not reach £8000, or a little more than one-fourth of the expenditure; and that the charities relieved last year 85,000 people, or nearly two out of every five of the entire population of the city.

Increase in Salaries of Poor-law Surgeons.

At the annual meeting of the Chipping Sodbury board of guardians held on April 30th Sir Gerald Codrington, the

Digitized by Google

chairman, stated that during the past year the board had increased the salaries of Mr. H. H. Williams, L.R.C.P., L.R.C.S. Edin., Mr. Alfred Grace, M.R.C.S. Eng, L.S.A., and Mr. W. J. Cox, M.R.C.S. Eng., L.S.A., the medical officers of the various districts of the Chipping Sodbury Union.

May 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Large Bequests to Charities.

THE sum of £39,000 has been allocated to Scottish charities from the estate of the late W. A. Guesdon, who died at Clapham on April 4th, 1891, and who bequeathed £400,000 to hospitals, &c., throughout Great Britain. The details for Scotland are:—

Scotland generally.—Queen Victoria Jubilee Hospital for Nurses, £5000; Orphan Homes of Scotland (Mr. Quarrier), £6000.

Edinburgh.—Royal Infirmary, £3000; Hospital for Sick Children, £1500; Orphan Hospital, £1500; Original Ragged School, £500; United Industrial Schools, £500; Edinburgh Hospital and Dispensary for Women and Children, £500.

Glasgow.—Hospital Sunday Fund for Royal Western and Victoria Infirmary, £5000; Hospital for Sick Children, £1500; Institute for Orphans and Destitute Girls, £2000; Sick Poor and Private Nursing Association, £1000; Glasgow United Evangelistic Association, £1000; Glasgow Industrial Schools at Mossbank (boys) and Maryhill (girls), £500.

Aberdeen.—Royal Infirmary, £2000; Royal Samaritan Fund, £1000; Aberdeen Industrial School for Boys (Oakbank), £250; Aberdeen Industrial School for Girls (Whitehall), £250.

Inverness.—Northern Infirmary, £2000; Highland Orphanage, £2000.

Dundee.—Royal Infirmary, £2000; Working Boys' Home, £500; Working Girls' Home, £500.

The Hospital Sunday Fund, Glasgow, gets the residue of the estate.

Glasgow University.

The University is to receive under the will of the late Dr. John Grieve the sum of £8000, which is to be applied at the discretion of the court to the foundation of a lectureship, fellowship, or scholarship. The present demand for teaching in the subject of public health is very inadequately met by the existing laboratory arrangements and the University Court has decided to equip a temporary laboratory until more satisfactory permanent dispositions are possible. Some recent communications with possible benefactors of the University render it probable that a lectureship in geology will shortly be instituted. The athletic side of university life is to be afforded a further opportunity by the erection of fives-courts. The demands which are to be made upon the medical student under the five years' curriculum in connexion with such special subjects as diseases of the eye, ear, throat, skin, &c., have not yet been issued in an authoritative form, though it is understood they have been formulated by the Senate. This delay is a matter for regret and it may lead to considerable inconvenience. The session is now far advanced and it may well be the case that when the additional regulations appear students will find in them requirements which they can now only meet by taking a number of extra classes in their last summer, amidst the anxiety and excitement of the final examination. Had the regulations appeared a few weeks earlier the student could have arranged to attend the compulsory courses during the present session. This would not only have consulted his convenience, but would have also increased the probability of his attendance being a profitable one.

Glasgow Medico-Chirurgical Society.

The following gentlemen have been elected office-bearers for the session 1896-97:—President, Dr. W. L. Reid. Section of Medicine: Vice-President, Dr. Alex. Napier; Councillors, Dr. R. B. Ness and Dr. Maitland Ramsay; Secretary, Dr. Hinshelwood. Section of Surgery: Vice-President, Dr. Newman; Councillors, Dr. Walker Downie and Dr. J. H. Nicoll; Secretary, Dr. John Barlow. Section of Pathology: Vice-President, Dr. T. K. Monro; Councillors, Dr. Lindsay Steven and Dr. Rutherfurd; Secretary, Dr. R. M. Buchanan. Section of Obstetrics: Vice-President, Dr. Samuel Sloan; Councillors, Dr. J. Nigel Stark and Dr. Edgar; Secretary, Dr. Lawrence Oliphant. Treasurer, Mr. Henry E. Clark; General Secretary, Dr. C. O. Hawthorne.

Medical Appointments, Glasgow.

Dr. J. B. McKenzie Anderson has been appointed assistant dispensary physician to the Royal Infirmary. Dr. John Wright is to succeed Dr. J. Boyd as casualty police surgeon in the western police district. The resignation of Dr. Ernest L. Marsh as senior assistant medical officer in the Belvidere Fever Hospital is announced. He is to be succeeded by Dr. Andrew Watson. Dr. Francis Gairdner has been appointed one of the junior medical officers to the hospital.

Broomhill Home for Incurables, Glasgow.

The annual sale of patients' work took place on the 9th inst., the sale being declared open by Sheriff Cowan, Paisley. There are at present in the home about 100 patients and those in receipt of out-door relief number nearly 200, the lack of funds preventing other applicants being placed on the books. The sale was largely attended, many of the best-known practitioners in the west of Scotland being present. The proceeds exceeded £250.

Aberdeen Royal Infirmary.

A three days' sale of work (including a "jumble" sale), promoted by the ladies' working party, took place last week in the Drill Hall, Woolmanhill, Aberdeen. The full proceeds, to be handed over to the Royal Infirmary, amount to rather more than £200. Dr. Robert John Garden, one of the surgeons of the infirmary, and Mrs. Garden took chief charge of the arrangements.

Aberdeen University Buildings Extension.

The executive committee met on May 8th, the Marquis of Huntly in the chair. A financial statement was submitted showing that the amount subscribed at March 20th, 1895 (the date of the late Mr. Charles Mitchell's additional offer of £6000), was £32,167 15*s.* 9*d.* The amount subscribed at the date of the meeting being £42,563 8*s.* 10*d.*, giving a difference of £10,395 13*s.* 1*d.*, the condition that £10,000 must be subscribed to secure the additional gift of £6000 has been fulfilled. The money thus raised will go towards the erection of the south wing. It is now expected that Government will give a further grant of £15,000 towards the scheme. The total sum collected up to May 8th was £109,563 8*s.* 10*d.*

May 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Public Health Bill.

THIS Bill has now been received from the Standing Committee on Law in an amended form and provides amongst other matters that the Local Government Board may invest a rural sanitary authority with the power of an urban sanitary one, that sanitary authorities in adjoining districts may combine for the execution of works, and that superannuation allowances to officers may be made in consideration of duties under the Public Health or under this new Act.

The City of Dublin Nursing Institution.

This institution, which is connected with the City of Dublin Hospital, has proved to be a great success. On the 9th inst. a large and very distinguished company were invited to an afternoon entertainment at 27, Upper Baggot-street, on the occasion of the presentation of an address and service of plate to the lady superintendent.

Belfast Hospital for Consumption and Diseases of the Chest.

At a meeting of the supporters of this hospital, held on May 5th, the following resolution was passed unanimously: "That the committee appointed by the resolution passed at an extraordinary general meeting of Feb. 3rd last, to prepare the draft of an agreement to carry out the proposed amalgamation of this hospital with the Forster Green Hospital for Consumption and Diseases of the Chest, having this day submitted same, this meeting approve in all respects of such draft scheme and agree to same, subject to our trustees obtaining the sanction of the Court of Chancery thereto." In accordance with this arrangement there will in the future be only one hospital for consumption and diseases of the chest in Belfast.

An Ulster Poor-law Board Superseded.

A sealed order has been forwarded by the Local Government Board to the Castleblaney Union removing the present board of guardians of Castleblaney from their office and appointing Mr. Agnew, Local Government Board inspector of Belfast, acting guardian for the time being. The reason for this step is the fact that the Poor-law guardians of that union refused to carry out the instruction of the Local Government Board with reference to the building of labourers' cottages in that union.

The Belfast City and District Lunatic Asylum.

At the meeting of the governors, held on May 11th, Dr. Cuming, in accordance with his notice of motion, moved: "That the commissioners of control be requested to advertise for competitive plans for the erection at Purdysburn of two chronic blocks for the reception of 300 patients, and such portions of the administrative buildings as are necessary for an asylum capable of containing hereafter 800 patients, with facilities for future extension to 1000 patients; and that the Purdysburn committee be requested to negotiate the special manner of carrying out the project, subject to the approval of the board." There can be no doubt that, as pointed out by Dr. Cuming, the present state of things as regards the disposition of lunatics in Belfast is a public scandal. A large number of patients are in the union workhouse who ought to be in the asylum instead of where they are, and we are constantly being confronted with expressions of public opinion to this effect, sometimes in the form of verdicts of coroners' juries and sometimes by other forms of protest. The asylum at present is notoriously overcrowded and the crying necessity for proper accommodation can be no longer put off. Further, owing to the overcrowded state of the asylum and to the statements made from time to time that the workhouse was not a suitable place for insane people, Dr. Cuming said a large number of insane people who ought to be placed in such an institution are being actually kept at their homes. It is high time that this state of affairs should be ended. Dr. Cuming's motion was carried and it is hoped it will tend to end the present deadlock.

The Battle of the Clubs at Cork.

The fight with the clubs at Cork has lost much of its local interest as the newspapers have ceased to insert any correspondence on the subject. The club members generally are anything but pleased with the present state of affairs, and they have been hoping against hope that something may occur to break up the organisation of the medical men, but there is not the slightest indication in that direction—on the contrary, many of the medical men are coming to realise that it would be better for the profession at large if the yearly contract system could be abolished completely and an arrangement instituted in its stead by which small payments per visit would be made by artisans and others who could not pay ordinary fees. The result of the contest in Cork so far has been that the profession has, in the aggregate, received a larger amount of money. Indeed, one Cork gentleman who resigned his clubs states that last year he received more in private fees from club patients than his salary would have amounted to, and his was by no means an isolated experience. The senior medical men, too, now receive fees from wealthy club patients who formerly paid miserable doles to club officers. Experiences of that kind as well as an admirable *esprit de corps* tend to weld together the medical men of Cork in defence of their common interests. The pitiable part of the whole business is that the poorer club members who have been cajoled by their richer brethren are obliged to avail themselves of the services of the imported club medical officers whether they have confidence in them or not. If those three medical men happened to be specialists in every branch of medicine it stands to reason that many of their patients would one time or another desire a change, but now the struggling artisan who is a member of one of their clubs not alone has no choice, but outside the three he cannot even have a consultation. It is very gratifying to the Cork profession to find that the movement of which they have been the pioneers has extended so rapidly over England. One good result they hope for is that a bond of union will be established between medical men all over the United Kingdom, and that thereby the dignity and the interests of the medical profession will be everywhere maintained.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Statistics of Scarlet Fever at the Hôpital des Enfants Malades.

THE Children's Hospital of the Rue de Sèvres received in 1885 256 cases diagnosed as scarlet fever. In nineteen instances there was an error of diagnosis, and two of these children contracted the disease during their sojourn in the wards. Be it noted that it was only as recently as Jan. 1st, 1896, that a separate ward was opened for these doubtful cases. The nett mortality was 5·85 per cent., a great improvement on previous figures, especially when we consider that half of the deaths occur in children brought in in a desperate condition. The other causes of death were broncho-pneumonia (3), secondary infectious sore throat (1), tuberculosis (1), and entero-gastritis of nurselings (2). The most frequently noted complications were early cynanches with white deposit (32 per cent.), generally of a mild type with creamy exudation, sometimes pseudo-membranous, and occasionally accompanied with nasal discharge, suppurating glands, and serious symptoms of infection; secondary cynanches, assuming generally the diphtheria type, but invariably streptococcic (only one of these cases died); suppurative adenitis (7 per cent.); and suppurative otitis (20 per cent.), appearing generally at the moment of the disappearance of the sore throat. Albuminuria was present in 20 per cent. of the cases, but in 8 per cent. this was only transient. In 6 per cent. the albumin was synchronous with the onset of the complication and disappeared with it. In only 6 per cent. was there scarlatinal nephritis properly so called, with anasarca and sometimes hæmaturia and anuria. Two-thirds of these cases of scarlatinal nephritis were acquired outside the hospital, six only contracting it in the wards where all the patients were put on strictly milk regimen. Pulmonary and pleural complications were very rare (broncho-pneumonia, always of a severe type, 5 per cent., and empyemata, 2 per cent.). Cardiac complications were still more rare, only one case of mild endocarditis being noted. Arthralgia (2 per cent.), synovitis (1 per cent.), and suppurative arthritis (1 per cent.) were also infrequent. In one case of suppurative arthritis the streptococcus was discovered, the pus from the rest of the cases being free from micro-organisms. Three-fourths of the cases of scarlet fever occurred between the ages of three and nine years. Above nine years of age the mortality was *nil;* in patients of one and two years of age it ranged from 50 to 11 per cent. The disease was most frequent in spring and summer, the complications most frequent in autumn, and the mortality highest in winter (22 per cent.) and nearly *nil* in summer and autumn (only one death from June to the end of November). Thirty-two children suspected of diphtheria received on their admission 20 c.c. of Roux's serum. Twenty-eight per cent. of these had serum eruptions (generally a fortnight after the injection), these being morbilliform and accompanied with joint-pains. In no instance were these rashes followed by serious symptoms and they invariably disappeared in from twenty-one to twenty-eight hours. Dr. Sevestre's remark that these measly rashes were more commonly associated with streptococcic sore throats was confirmed at the Hôpital des Enfants Malades. Two trials of Marmorek's serum were not encouraging in their results. The routine treatment pursued was strict milk diet, acetate of ammonia (1 or 2 grammes daily during the eruptive stage), buccal irrigation, with aromatised boiled water, and the injection into the nasal fossæ of mentholated oil. Despite these precautions and the low mortality the morbidity in the scarlet fever wards was high, 43 per cent. of the patients having been affected with complications (secondary sore throats, otitis, suppurating glands, albuminuria, broncho-pneumonia, &c.). This morbidity is ascribed to the defective state of the wards, the scarlet fever cases (like the measles cases) being lodged in rooms which are too small, too dark, and generally antiquated, and there being no wards wherein to isolate the children suffering from complications. Funds for the construction of new wards have been set aside for some time by the Assistance Publique, but red-tapeism blocks the way.

Massage in the French Army.

The Minister of War has decreed that hospital orderlies shall in future be taught the art of massage. Classes for

Digitized by Google

this purpose will be instituted in Paris (Val-de-Grâce Hospital), at Lyons (Hôpital Desgenettes), and at Algiers (Hôpital du Dey). After a six weeks' course the pupils will be distributed amongst the principal military hospitals.

May 12th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Sanitary Precautions.

THE Public Health Department continues to receive grave intelligence from Egypt as to the spread of cholera, and particularly from Alexandria, where it assumes ever more threatening proportions. The persistence of the epidemic during the winter in the Arab quarters strengthened the anticipation that with the advance of the year, the rise in temperature, and the return of the pilgrims after the feast of Ramadan it would develop accordingly. From the close of December, indeed, the Public Health Department had promulgated precautions of a general kind in advance, and more recently—from the close of February—it had arranged with the Posts and Telegraphs Department that their vessels plying between Massowah and Alexandria should till further notice cease to touch at the latter port. The primary object of this prohibition was to prevent the importation of cholera by means of the military transport services. Further regulations are now in force for special medical surveillance of the vessels plying between Alexandria, Naples, Venice, and Genoa—a "servizio di vigilanza," in fact, conducted on board every arrival at the three last-named ports. In addition to these measures there have just been despatched to all the prefects of the maritime provinces of the kingdom special instructions for the rigorous enforcement of all the regulations established by the central sanitary authority in times of anticipated cholera invasion.

A New Method of Embalming the Dead.

One would have thought that the annually increasing adoption of cremation would have minimised the attempts in which Italy has always been prolific to preserve the dead subject, whether by petrifaction, or mummification, or embalming. But such is not the case. In THE LANCET of Sept. 14th, 1895, was described the perfection to which the lately deceased Neapolitan naturalist, Dr. Girolamo Segato brought the first-named method, his triumphs in petrifying the *cadaver humanum* forming one of the chief attractions of the Florentine Museum. Still more recently Signor Carlo Vercelloni of Lecco has invented another and more ingenious process by which the dead subject is subjected to the slow, continuous action of chemical exhalations liberated from the walls of the coffin in which the corpse is hermetically sealed. After a series of experiments on asses, cats, and birds, he found he could by this means absorb the gases of decomposition and humidity in the dead subject and gradually bring about the mummified state—that of perfect dryness of the subject, retaining every feature exactly as in life. Beginning on July 10th, 1895, with the dead body of a male child of six who had died of meningitis he succeeded in effecting the condition of what he terms "mummimbalsamation"—the head, trunk, and limbs being admirably preserved in the anatomical relief of nature, the expression stereotyped, the hair blonde as in life, only the complexion of the body being of that yellowish copper colour peculiar to mummies, and the eyes, of course, losing their liquid lustre. These, however, being veiled by the eyelids and eyelashes, detract in no way from the look of repose which characterises the *ensemble*. Belonging to the curiosities of science rather than to its utilities, Signor Vercelloni's method may yet be adopted in cases where it is of special interest to preserve the dead subject "in his habit as he lived." But these, as I have indicated, must be rare, and increasingly so with the advance of cremation, itself a revival of an ancient practice. I may add that Signor Vercelloni's experiment is on view at the Ospedale Maggiore in Milan.

May 11th.

MESSRS. THOMAS DE LA RUE AND CO., Limited, of 110, Bunhill-row, E.C., have sent a donation of 100 guineas to the Royal Chest Hospital, City-road, towards the fund now being raised in connexion with the festival dinner to be held at the Hôtel Métropole on the 26th inst.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Amended Regulations for the Twelfth International Medical Congress.

ALL who have followed the controversy on the subject of the exclusion of English from the languages officially admitted to the discussions at the International Medical Congress will be glad to hear that the executive committee has yielded to the expressions of opinion which have appeared on this subject in both the English and French medical press. Professor Erismann, the general secretary of the Congress, has sent me a formal letter announcing this fact and also the fact that certain specialities which had originally been included under the general headings of medicine or surgery have been raised to the status of independent sections. The letter announcing these changes is written in French, and as it is headed "avec prière d'insertion" I transcribe it *verbatim*.

"Les explications données, il y a environ deux mois, par le Comité exécutif concernant les Sections 7 et 21 du Règlement du Congrès, qui traitent de la question des sections et des langues, ont pu convaincre nos confrères étrangers et russes qu'en discutant et en rédigeant ces sections, ni la Faculté de Médecine de l'Université de Moscou, ni le Comité exécutif n'ont eu l'intention de créer à l'activité des représentants des diverses spécialités et des diverses nationalités plus de difficultés que n'en comportent (comme il nous semblait) la réussite du prochain Congrès et le développement ultérieur des Congrès Internationaux de Médecine en général. Avant de prendre une décision quelconque, nous avions tenu compte des avis que les nombreux et importants organes de la presse médicale avaient fait entendre après le Congrès de Rome. Nous avions cru pouvoir en conclure que nos confrères de tous pays considèrent la multiplicité des langues et un fractionnement trop considérable du Congrès en sections comme des conditions pouvant nuire à ces assemblées et en affaiblir l'importance. Cet avis se trouvant partagé en principe par la majorité des membres de la Faculté de Médecine, celle-ci avait adopté la rédaction connue des Sections 7 et 21. Toutefois, à l'heure actuelle, il est hors de doute pour nous que beaucoup de nos confrères étrangers, de nos futurs hôtes, ne sont pas satisfaits des prescriptions de ces Sections du Règlement et trouvent qu'elles se concilient mal avec les besoins réels du Congrès et sont dangereuses pour son succès. Pénétrés du désir sincère de faire tout ce qu'il est possible dans l'intérêt du prochain Congrès et plaçant sa réussite au-dessus de toute considération personnelle, même basée sur l'idée de faire entrer dans la pratique des Congrès des principes qui nous semblaient essentiels et utiles, nous reconnaissons volontiers que notre tentative était inopportune. C'est pourquoi nous avons décidé de proposer au Comité d'Organisation du Congrès (dont font partie, entre autres, tous les membres de la Faculté de Médecine de notre Université) de donner au Section 7 une rédaction qui exprimât clairement l'indépendance de certaines spécialités, rattachées jusqu'à un certain point à d'autres branches par l'ancienne rédaction, et de modifier la Section 21 de telle façon que la langue anglaise soit admise dans les travaux des sections à l'égal du français, de l'allemand, et du russe. Le Comité d'Organisation a pleinement accepté notre proposition et dans sa séance du 19 Mars, 1896, a adopté la rédaction modifiée des Sections 7 et 21 telle que nous lui avions soumise.

(Signed) "Le Secrétaire-Général, F. ERISMANN."

It will be remembered that originally the Congress was divided into twelve sections, the names of which appeared in THE LANCET of Feb. 22nd (p. 522). They have now been extended to fifteen, as follows: (1) Anatomy (Anthropology, Normal Anatomy, Embryology, and Normal Histology); (2) Physiology (including Medical Chemistry); (3) General Pathology and Pathological Anatomy; (4A) General Therapeutics (including Hydro-therapeutics, Climato-therapeutics, &c.); (4B) Pharmacology; (4C) Pharmacognoscy and Pharmacy; (5) Internal Diseases; (6) Pediatrics; (7) Nervous and Mental Diseases; (8) Dermatology and Venereal Diseases; (9) Surgery; (9A) Odontology; (10) Military Medicine; (11) Ophthalmology; (12A) Otology; (12B) Laryngology and Rhinology; (13) Midwifery and Gynæcology; (14) Hygiene (including Sanitary Statistics, Social Medicine, Epidemiology, Epizootology, and Technical Sanitary Science); and (15) Legal Medicine. The following note is added: "In case of necessity supplementary sections can be organised." It will be observed that there are really in all nineteen sections, but presumably those numbered with letters in addition to numerals—as, for instance, 4A, 4B, and 4C—are intended to rank together as sub-sections of one great section. If this be so, the only specialties which have become independent sections are military medicine, ophthalmology, and the three subjects, otology, laryngology, and rhinology. The paragraph in the regulations relating to languages (Section 21) in its amended form runs as follows: "French is recognised as the official language of the Congress for all international relations. In the general meetings communications will be permitted in other European languages. As regards

Digitized by Google

ommunications and discussions in the Sections of the Congress they may take place in French, German, English, and Russian." On this point (the admission of the English anguage) Professor Erismann has, in a private letter to me, ade a request which both he and the executive committee elt some hesitation in making formally and publicly, but hich may fittingly find publicity in the columns of THE ANCET. It is to this effect, that as the Russian hosts will henever possible speak at the Congress in either French or erman rather than in their own language, so they would sk their English guests to similarly refrain from speaking n English whenever they are able to speak in French, which s still the official language of the Congress. A ready comliance with this request would tend to diminish some of the vils which have undoubtedly been felt in previous Congresses rom the use of a multiplicity of languages.

The Russian Jenner Commemoration.

The Russian National Health Society have found it lesirable to postpone the Jenner centenary celebration until October, partly because the extensive preparations which are eing made to ensure the success of the celebration could ot be completed by May 2nd (14th), and partly on ccount of the coronation festivities which will begin very hortly. In all probability the day chosen for the Jenner elebration will be Oct. 12th (24th), the anniversary of he first inoculation of small-pox in Russia. It will be emembered that on that date, in 1768, the Empress Catherine was inoculated by Dr. (afterwards Baron) Dimsdale under circumstances already recorded in THE LANCET.[1]

St. Petersburg, April 26th (May 8th).

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Alexandria.

DURING the past fortnight there have been sixteen new admissions into cholera hospitals and nine deaths, besides nineteen deaths outside hospitals. Eleven of these deaths occurred in the last twenty-four hours, and included a well-known Dutch gentleman who was chief secretary to the municipality and who is said to have been restricted to milk diet for some weeks. In Tantah there has been one and in Zagazig there have been two fatal cases; also one at Suez and one at Kinghi Osman, a village near Alexandria. The important point is not so much the greater number of cases, but rather their geographical distribution in several quarters of the town, not excluding the neighbourhood of the Mahmoudieh Canal, which is the only water-supply for the city. Cholera has now been present in Alexandria since December, and no one could have worked harder in trying to stamp it out than Dr. Rogers, who has frequently visited the town, and Dr. Bittar, the local sanitary inspector. But outside the Sanitary Department it is difficult to find anyone to praise. There has been an incredible amount of passive opposition on the part of Egyptians and the lowest class of Europeans. No mild cases have yet been reported to the authorities and there has been habitual concealment of the disease throughout. The ignorant local press, both French and Egyptian, has talked since the beginning in slighting terms of the *soi-disant* cholera, while other papers more hostile have published articles accusing the medical practitioners of turning the hospital into a *morgue*. Small wonder that an ambulance waggon was attacked and that the greatest difficulties have been placed in the sanitary officers' way. Crass ignorance is not confined to the poorest natives, for it was gravely announced at a council of Ministers that the medical men were in the habit of throwing a yellow handkerchief over the face of a suspected cholera patient, of rendering him insensible, and of thus conveying him to the hospital. It is impossible to trace the seed from which this malignant absurdity has sprung, but it reminds one of the dark days about ten years ago when the cholera doctors were stoned in Naples! Last week the Governor of Alexandria permitted a great concourse of Nubians there in honour of a dead Sheikh, and the sole excuse for him is that this annual festival is not officially written upon the list of fairs which were all ordered to be suppressed because of the cholera. The authorities are getting used to dropping cases of the disease and are no longer taking stringent precautions. The European Consuls, excepting the French representative, decided at the beginning of the winter to waive their capitulation rights and to allow the municipality to deal with protected subjects in cholera houses in the same way as with natives. I am glad to be able to report that even the French have allowed a Moor, who is legally under their protection, to be dealt with as if he was an Egyptian subject. The Mahmoudieh canal is being kept under constant supervision by watchmen under the control of Sanitary Inspectors Pinching and Garner, and every precaution is being taken to prevent pollution. The Soudan expedition has already caused great economies in all departments and the much-needed £40,000 for improving the water-supply and the public latrines of Cairo has been withdrawn—let us hope only temporarily.

Filtered Water for Alexandria.

Dr. Bitter has just reported to the municipality the result of his experiments during twelve months, for which £4500 were generously voted. He finds that the ordinary sand filter bed as used in Europe is practically of no avail because the canal water during the whole year holds in suspension excessively fine clay which blocks the filter-beds. Both on financial and technical grounds he reports also against blocks of compressed sand and Breyer's asbestos system. All his experiments tend to show that the water of the Mahmoudieh Canal cannot be well filtered unless the clay is first eliminated. Anderson's iron filings system acts well except at high Nile, but he has found, on the whole, that chemical agents such as permanganate of potash or soda act best by precipitating the clay in suspension before filtration through sand. But before advising the construction of filter-beds and two decanting basins he advises the delay of a few months to see whether underground water cannot be found and supplied to the town at about half the cost of installing filter beds. Borings to the depth of 40 metres have already been made and yield hopeful results. The visitors at Mena House, near the Pyramids, have been drinking very pure water for eight years from a boring in the desert, and it is quite possible that every town in Egypt could be supplied in the same way. But this would require a geological survey and the creation of a special boring department, as already proposed by Rogers Pasha.

British Troops at Wady Halfa.

The North Staffordshire Regiment and details now number 930 men in barracks, and the sick-rate is only 5 per cent., and even that is chiefly venereal. It compares very well with the sick-rate of the troops in Cairo (6·7 per cent.) and those in Alexandria (6 per cent.) There is one case of enteric fever, but that was contracted before arrival at Wady Halfa. Surgeon-Major Sloggett and Surgeon-Captains Holmes and Carr are in medical charge, with one quartermaster and twenty-six hospital orderlies. There is a permanent hospital of 100 beds and an officers' hospital for the English officers of both armies. During the last month three officers have been admitted for hepatitis, dysentery, and conjunctivitis. On the whole the health of the troops is and has been excellent. The average temperature of the first half of April has varied from a minimum at night of 58° or 63° to a maximum by day of 101° F. Fortunately it is very dry, the humidity ranging from 21 to 28 per cent. The medical staff in Egypt has been increased by four officers and all leave has been stopped for the whole summer.

Cairo, May 6th.

FOREIGN UNIVERSITY INTELLIGENCE.—*Copenhagen:* Dr. Bjerrum has been appointed Professor of Ophthalmology in succession to Dr. E. Hansen Grut, resigned.—*Heidelberg:* Dr. Passow of Berlin has been appointed to an Extraordinary Professorship of Otology.—*Leipzig:* Dr. Otto Fischer has been appointed Extraordinary Professor of Physiological Physics.—*Philadelphia (Jefferson College):* Dr. Albert P. Brubaker has been appointed Assistant Professor of Hygiene.—*St. Petersburg (Military Medical Academy):* Dr. M. V. Yanovski has been appointed to the Chair of Diagnosis and General Therapeutics, in succession to the late Professor Chudnovski. Drs. Simanovski and Sirotinin have been promoted to Ordinary Professorships of Laryngology and Clinical Medicine respectively.—*Vienna:* Dr. A. Haberda has been recognised as *privat-docent* in Forensic Medicine.

Obituary.

JAMES SEATON REID, M.D., L.R.C.S. EDIN., L.S.A. LOND.

WE regret to announce the death of Dr. Seaton Reid, the father of the profession in Belfast, which took place at his residence in that city on May 3rd, the cause being exhaustion following an attack of pneumonia. For some time previous to his decease Dr. Reid had retired from active practice, but for a period of half a century he was one of the leading medical men in the north of Ireland. Dr. Reid, who at the time of his death was in his eighty-fifth year, was born at Ramelton (county Donegal) on July 11th, 1811, his father being a Presbyterian clergyman in that place; while his uncle, after whom he was named, was Professor of Ecclesiastical and Civil History in Glasgow University and wrote a celebrated book, "The History of the Presbyterian Church in Ireland." Dr. Reid, after studying in the old Belfast College, went to Edinburgh, where in 1832 he obtained the L.R.C.S. Edin. and in the following year graduated M.D. of Edinburgh University. He began practice in Londonderry, where from 1833 until 1836 he was house surgeon in the County Infirmary. On leaving Londonderry for a time he was resident medical officer in the General Penitentiary, Millbank. Soon afterwards he went to Belfast, and when in 1840 the board of health opened a second fever hospital he was appointed physician to it. It was here that he first gained an experience in fevers, a form of disease in which he was for years the accepted authority in the north of Ireland. In 1846 he was appointed physician to the fever hospital in connexion with the union workhouse, a post he held for almost half a century and where he had an unrivalled amount of cases of fever and acute disease from which to acquire a great experience. In 1857, on the death of Dr. Horatio Stewart, he was chosen Professor of Materia Medica in Queen's College, Belfast, an appointment which he held until 1890. On the establishment of the Royal University of Ireland he was selected as one of the first examiners in materia medica, and for several years he continued to act in that capacity. He was also for a time physician to the Belfast General (now Royal) Hospital. He wrote Statistical Reports on Contagious Fevers and on the Classification of Irish Fevers, and on Heart Disease, Addison's Disease, and on aneurysm. These communications appeared principally in the *Dublin Quarterly Journal*. He was an ex-president of the Ulster Medical Society and of the Belfast Clinical and Pathological Society. It will be thus seen what varied posts Dr. Reid held during his lengthened professional life and what opportunities he possessed for gaining a sound experience. No one could meet Dr. Reid without feeling he was a very strong personality. Stoutly built, of a florid complexion, with an abundance of snow-white hair, and most punctilious in the care with which he dressed, Dr. Reid in former times was a very striking figure in Belfast. Many of the present younger generation of medical men had no opportunity of knowing him, but those who did could not fail to be struck with the soundness and correctness of his opinion. He certainly believed largely in Sydenham's doctrine that "Tota ars medicinæ est observatio," but old students who attended his private clinique for members of his college class at the Union Hospital will recall his great carefulness in diagnosis. Somewhat dogmatic in manner, always decided in his opinion and action, Dr. Reid was a true friend, a hospitable entertainer, and a most kindly and honourable member of the medical profession. He was buried in the Belfast Cemetery on May 6th, almost all the medical men in that city being at his funeral.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths are announced of the following eminent foreign medical men:—Dr. Richard Hodges, Assistant Professor of Surgery in Harvard University.—Dr. Boffin, Professor of Clinical Surgery in the Nantes Medical School.—Dr. D. van Haren Noman, Professor of Dermatology in the University of Amsterdam.—Dr. A. Sacré, Prosector and Assistant Surgeon of the Brussels hospitals, at the age of thirty-six. He was the son of Professor Sacré, also of Brussels.—Dr. Roberty, formerly Professor of Physiology in the Marseilles Medical School.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination in Anatomy and Physiology for the diploma of Fellow:—

Monday, the 11th inst.:

James Andrew Neptune Scott, M.R.C.S. Eng., M.D. & C.M. Glasg., L.R.C.P. Lond., Glasgow University; Arthur Godfrey Ince, M.R.C.S. Eng., L.R.C.P. Lond., Charing-cross Hospital; Charles Ernest Mackenzie Kelly, M.R.C.S. Eng., L.R.C.P. Lond.; David Storer Wylie and Harold Holkar Broome, Owens College, Manchester; and Herbert Sherwell Clogg, University College of South Wales, Cardiff.

Fourteen gentlemen were referred back to their professional studies for six months.

Tuesday, the 12th inst.:

Herbert Wolseley-Lewis, M.R.C.S. Eng., L.R.C.P. Lond., Westminster Hospital; Edward Owen Thurston, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's Hospital; Henry Allcroft Duffett, M.R.C.S. Eng., L.R.C.P. Lond.; Clarence William Hewlett, M.R.C.S. Eng., L.R.C.P. Lond., and Lancelot Wilkin, Guy's Hospital; George Stanley Dodgson, Cambridge University and Middlesex Hospital; and Edward Joseph Fox, Owens College, Manchester.

Nine gentlemen were referred back to their professional studies for six months.

CONJOINT EXAMINATIONS IN IRELAND BY THE ROYAL COLLEGE OF PHYSICIANS AND THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following gentlemen have passed the examination for the diploma in State Medicine:

Frederick Christian Augustus Bushman, L.R.C.P. & S. Irel.
Surgeon-Major Francis Joseph Doyle, F.R.C.S. Irel.

THE UNIVERSITY OF LONDON.—The general meeting of Convocation was held on May 12th at Burlington-gardens, Mr. E. H. Busk, Chairman of Convocation, being in the chair. Mr. H. J. Harris presented the report of the annual committee. It was announced that Mr. T. B. Napier had been elected Fellow in place of the late Sir W. S. Savory, and that the vacancies caused by the deaths of Sir G. Buchanan, Mr. T. H. Huxley, and Sir Julian Goldsmid had been filled by the election of Mr. C. Hubert H. Parry, Mus.D., Professor W. F. R. Weldon, and Mr. Arthur Milman. The vacancy arising from the resignation of Mr. R. H. Hutton will, according to the provisions of the charter, be filled by Convocation in June. Mr. Stanley Boyd moved the reception of the report of the special committee with respect to points in the scheme of the Royal Commission to be presented to the Statutory Commission. The principal recommendation of that report was the appointment of a special committee consisting of the chairman of Convocation, Dr. Allchin, Mr. Bompas, Mr. Stanley Boyd, Dr. Cave, Mr. Cozens-Hardy, Mr. Thiselton Dyer, Dr. Napier, and Dr. S. P. Thompson. The resolution was carried. The following resolutions—(1) "That a special committee of thirteen members, including the Chairman of Convocation, be nominated to prepare for presentation to any Statutory Commission which may be appointed a memorandum of points in the scheme of the Royal Commission in which modification is desirable, and with power to confer with such said Statutory Commission and with the Senate or any committee thereof"; and (2) "That this special committee consist of the following members: the Chairman of Convocation, Dr. Allchin, Dr. Benson, Mr. Bompas, Mr. Stanley Boyd, Dr. Cave, Mr. Cozens-Hardy, Mr. Thiselton Dyer, Dr. Heber Hart, Dr. Napier, Mr. Blake Odgers, Dr. Sansom, Dr. S. P. Thompson"—were also carried. Mr. Stanley Boyd moved: "That the new and enlarged special committee recommended for appointment in the report of the special committee on the memorandum to be presented to such said Statutory Commission should have full powers, if it thinks fit, to prepare amendments to the London University Commission Bill and to have them proposed on behalf of Convocation in either House of Parliament." The resolution was carried.

LITERARY INTELLIGENCE.—Messrs. P. S. King and Son, of King-street, Westminster, announce that they

Digitized by Google

have in preparation a General Index to Hansard's Parliamentary Debates from the year 1830 to 1891. These volumes are numbered from 1 to 356 of the Third Series. The index will be published in four royal octavo volumes, price £10 10s. Special pains will be taken to make it exhaustive and the cross references as full and complete as possible. The debates will be indexed both under the subject of the debate, motion, or Bill, and under the name of the peer or member taking part in the debate. A suggestion made by Mr. Gladstone has been adopted—viz., that "the really historical declarations of Ministers and leading men" should be specially indicated. The work is being executed by Miss Nancy Bailey, who was for five sessions (1889-91, 1893-94) the indexer of Hansard's Parliamentary Debates. The index will without doubt be indispensable to politicians, historians, and literary men in general.—We understand that the second and final series of "Illustrations of Pathological Anatomy," by Professors Cast and Rumpel, is in the press, and that Dr. Voelcker, pathologist to the Middlesex Hospital, has undertaken to revise and edit the English edition. The first series, it may be remembered, was edited by Dr. Ruffer before his serious illness which necessitated his departure to Egypt. This work is unique, it being the only one extant in which the illustrations are painted from nature immediately at death, and hence are portrayed exact pathological conditions of disease otherwise unattainable. The English publishers are Messrs. Baillière, Tindall, and Cox.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Barnsley and District Hospital Saturday and Sunday Funds Committee has handed £1000 to the governors of the Beckett Hospital.—The committee of the Great Northern Central Hospital, Holloway-road, has received £1100 from a lady to endow a bed in memory of her late husband, and also, from an anonymous donor, £1050, to endow bed No. 7 in the Victoria Mary Ward.—The workmen of Sir W. G. Armstrong and Co., at Elswick, Newcastle, have contributed £464 6s. 1d. to the local medical charities for the quarter ending March 31st last, of which sum £335 1s. 1d. has been apportioned to the Royal Infirmary.—The Court of Common Council, London, has granted 100 guineas to the East London Hospital for Children, Shadwell.—In response to the appeal for funds to complete the building, furnishing, and equipment of the new hospital, Birmingham, the committee has recently received the following donations: namely, Anon. (A. A.), £500; Mr. W. B. Gibbins, Ettington, £100; Mr. G. S. Albright, £500; Mr. Richard Cadbury, £1000; Mr. J. W. Wilson, M.P., (second donation), £100; Mr. W. A. Albright, £500; Mr. W. H. Lloyd, Wednesbury, £100; and Mrs. Gibbins, £100.—The secretary of the National Hospital for the Paralysed and Epileptic, Albany Memorial, Queen-square, Bloomsbury, has received a donation for the current year of £105, made towards the support of the Convalescent Branch by the Worshipful Company of Mercers on account of the Earl of Northampton's Charity, and also of £100, being the share allotted to this hospital from the residuary estate of the late Miss E. C. Darling, by the executors.—The committee of the Dental Hospital of London, Leicester-square, has received £105 from Sir Henry Peek, Bart.—The late Mr. William E. Yates of Westwood, Leeds, has bequeathed £200 each, free of legacy duty, to the Leeds Public Dispensary and the Leeds Hospital for Women.—The board of management of the National Hospital for Consumption, Ventnor, Isle of Wight, has received a further grant of 100 guineas from the trustees of the Earl of Northampton's Charity.—The treasurers of the Middlesex Hospital have received a donation of 100 guineas from Her Majesty the Queen.

TYLDESLEY NEW SEWAGE WORKS, MANCHESTER.—The area over which the Tyldesley district council has control is 2489 acres in extent, it has a population of about 14,000, its ratable value is £61,000, and the quantity of sewage to be treated averages about 300,000 gallons daily. Some years ago a farm of 132 acres at Astley, about two miles from Tyldesley, was purchased for £14,000 and used as a sewage farm, the sewage being treated by broad irrigation and land filtration. But in 1894 the Mersey and Irwell Joint Committee deemed the works at Morley's Hall Farm unsatisfactory, the tanks being only capable of dealing with 12,000 gallons a day, while the actual flow was about 300,000 gallons, so it is not surprising that the effluent was condemned. Proceedings were taken by the committee in 1894 and the council was fined £20 and costs. Various methods of sewage treatment were examined, and it was decided eventually to adopt the system of the Magnetite Sewage and Water Purification Company of Manchester, who agreed to construct the whole work for £3250. The sewage is carried on to filter-beds composed of layers of "magnetite," a kind of ironstone, with a top layer of sand. These filter-beds are self-regulating, and the top layer of sand is cleansed by reversing the flow of one filter and allowing it to force itself upwards through the next filter. The floating matter from the top of the sand then runs into a well, from which it is pumped into "detritus tanks." After leaving these tanks the precipitant is added to the sewage by means of a Kierby mixer, worked by a water-wheel turned by the flow of the sewage. The cleansed sewage then passes through a "mixing race" to the inlet channels and to the precipitation tanks, which have been constructed with concrete bottoms and with walls faced with salt-glazed brick. There are eight filter-beds, each 33 feet by 16 feet. The precipitant used is "ælite," principally alumina, iron, and oxide of magnesium. The new arrangement is capable of dealing with some half-million gallons daily, so that it is believed that the needs of the township will be satisfied for some years to come. At the recent formal opening of the works Dr. Duncan, the chairman of the council, presided. Dr. Lowe, chairman of the Sewerage Committee, before declaring the works open, was presented with a handsome key on behalf of the Magnetite Company. He stated that the council had a ten years' indemnity from the company against any proceedings by the Mersey and Irwell Joint Committee on condition that the council made use of the company's precipitant. Mr. Sergeant, the medical officer of health for the county of Lancaster, expressed great interest and said the system was a departure from any he had seen before and he hoped it would prove a success. In appearance the effluent was very much like ordinary drinking water, and it is expected to be still better after the works have been in use some little time.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Cost of the Vaccination Commission.

In the course of answering a question across the floor of the House Mr. Hanbury, Secretary to the Treasury, stated that the total cost of the Royal Commission on Vaccination up to March 31st last was £16,792.

Colliery Explosions.

Steps are in progress for securing that the provisions of the Coal Mines Regulation Bill having special reference to coal-dust and the prevention of explosions in mines shall be passed into law in the course of the present session.

Poor-law Officers' Superannuation Bill.

Proposals have been made for the extension of the provisions of this measure to Ireland, and the Government has intimated that it will offer no opposition to them.

Public Health (Scotland) Bill.

During the Committee stage of this measure in the House of Lords the Earl of Rosslyn raised the question of the position of the chief medical officer in Scottish counties, and moved an amendment requiring that all reports by other medical officers in the county and sanitary inspectors should be transmitted to the County Council through him, and that he should have practical control of all matters of sanitation and public health. He pressed the amendment as necessary to avoid friction in the county administration. The Government, however, would not accept the amendment, preferring that the County Council should be left with a free hand to deal with the matter by means of its by-laws.

Accidents with Petroleum Lamps.

A Select Committee of the House of Commons, presided over by Mr. Mundella, is taking evidence with regard to the sale, storeage, and conveyance of petroleum and accidents arising in the use of petroleum lamps, and in the course of the proceedings on Wednesday, May 13th, Mr. Boverton Redwood, the petroleum expert, handed in for the use of the Committee the report of THE LANCET Commission on the subject of dangerous lamps.

HOUSE OF COMMONS.

TUESDAY, MAY 5TH.

Visiting Fever Patients.

Mr. H. C. Richards asked the President of the Local Government Board whether his attention had been called to an inquest held by Mr. Braxton Hicks on Dec. 31st last at Battersea on the body of James Stevens Romaine, who died at his home from malignant scarlet fever, at which it was proved that previously to his death his brother had been

Digitized by Google

removed to the Tooting Fever Hospital suffering from the same complaint, and that during the interval both parents had visited the child at the hospital every day, thus going to and from places where infectious disease existed; if he was aware that the jury expressed a strong opinion that the Metropolitan Asylums Board should be asked to revise their rules so as to lessen the risk of infection to the public by disallowing such visits unless under exceptional circumstances; that with regard to visiting patients, by the rules of the Board two visitors are allowed daily to each patient, limited as a rule to a quarter of an hour; that visitors are warned that they run great risk at entering the hospital, but that they are allowed to sit by the bedside; that the only protection to such visitors is a cloak placed over their clothes; and that, on leaving the hospitals, the visitors of necessity return home in public conveyances; and whether, in view of these facts, he would make representations to the managers to revise the rules in accordance with the suggestion of the jury.—Mr. Chaplin replied: I have communicated with the managers of the Metropolitan Asylums District and am informed that there has been no suggestion that the death of the child referred to was due to infection from the hospital, that visits to patients are only allowed under exceptional circumstances—namely, when patients are dangerously ill—and that such visits are limited to the nearest relatives or intimate friends of the patients. With regard to the statement that visitors of necessity return home in public conveyances, it appears that the father and mother in the case in question walked home and did not go into any public conveyance, and the regulations of the managers expressly urge visitors not to enter any omnibus, tramcar, or other public conveyance immediately after leaving the hospital. The managers have stated that the regulations as to the visiting of patients dangerously ill have been found to work smoothly and satisfactorily during the many years they have been in operation and that they see no reason for amending them as was suggested. They added that the enforcement of regulations to prevent parents of patients in the managers' hospitals (most of whom are young children) visiting them when dangerously ill or dying would only have the effect of largely discouraging, even if it did not wholly prevent, many parents from sending their children for isolation to the hospitals and of increasing rather than checking the spread of disease.

THURSDAY, MAY 7TH.

Poor-law Children in Canada.

Mr. Chaplin, in reply to Mr. S. Smith, said that the Canadian Government have provided for an annual inspection of children sent out to Canada by boards of guardians in this country, but not for an inspection of each child each year. It would undoubtedly be very much more satisfactory if the children were more frequently visited, and he would take the necessary steps with a view to communicating with the Dominion Government on the subject.

The Vaccination Question.

Mr. Logan asked the President of the Local Government Board whether his attention had been called to a statement recently made by their clerk to the guardians of the Warminster Union to the effect that he had inquired of the Local Government Board's vaccination inspector what would be the result of the report of the Royal Commission on Vaccination, and that the said inspector informed him that the Act would be so amended that the penalty would be imprisonment after the second offence; and whether such statement was made by the Board's inspector, and, if so, whether with or without authority; and, in the latter case, whether he would give such instructions as should for the future prevent the officials of the Board from spreading unauthorised assertions, which were easily mistaken for official announcements.—Mr. Chaplin said he was informed that the inspector who visited the Warminster Union had no recollection of having made a statement to the clerk of the guardians on the subject referred to in the question, and that if in conversation with the clerk the matter came under discussion it would have been impossible for him to have announced what would be the result of the report of the Royal Commission on Vaccination for the reason that he had no knowledge whatever of the views of the Commissioners.

Old Horses for Food.

Mr. Wootton Isaacson asked the Secretary of State for the Home Department whether his attention had been drawn to a case which recently came before Mr. Mead, at the Thames Police-court, brought by the Royal Society for the Prevention of Cruelty to Animals, when two horses were stopped which were being led to the docks for exportation to Rotterdam, both of which were suffering from disease; whether he was aware that diseased horses were daily shipped to Rotterdam for the purpose of being slaughtered and prepared for human food, when they were reshipped to this country in the form of sausages and tinned meats, and that this practice had been carried on to a considerable extent for some time, and whether he would take means to put a stop to a business so dangerous to health.—Sir Matthew White Ridley replied: I have seen reports in the newspapers of the case referred to and have communicated with the learned magistrate before whom it was heard. The two horses were being conveyed to Rotterdam presumably as they were past work for the purpose of being slaughtered for food. There was no evidence, however, that the horse in respect of which the conviction took place was suffering from any disease rendering it unfit for food; it was lame on one leg in consequence of a contracted tendon and a diseased foot. There is no doubt, I believe, that horses in a similar condition are frequently shipped to Rotterdam, but I have no evidence that a trade in diseased horses is carried on or that the food prepared from their carcasses reaches this country nor have I any power to prevent the business in question.

University of London.

Sir John Gorst, in reply to Sir Albert Rollit, announced that a Bill on the subject of the re-organisation of the University of London was being prepared in the Privy Council Office, but it had not yet received the sanction of the Government. When it had received that sanction it would probably be introduced in the House of Lords.

FRIDAY, MAY 8TH.

London Fever Hospital.

Mr. Chaplin, in answer to Mr. P. O'Brien, said he was informed that the new ward pavilion now being erected on the premises of the London Fever Hospital was intended for the reception of fever patients, that it was to take the place of an existing ward pavilion which was much larger, and that the result of the new erection would be to diminish the number of fever patients received on the hospital site by nearly one-half. The committee of the hospital, acting for the governors of the institution, were, he was informed, responsible for the new erection. The hospital in question had been in existence on the same site for some fifty years past. He assumed, as was the case with all new buildings in London, that plans of the new pavilion had been submitted to the authorities having the control of such matters within the metropolis. He had no power of control or action in the matter.

MONDAY, MAY 11TH.

Treatment of Imbecile Children.

Mr. Luttrell asked the President of the Local Government Board whether his attention had been drawn to a return made by the Poor-law Schools Committee to the effect that there were in the Metropolitan Poor-law schools 105 children mentally deficient, 20 liable to fits, and 8 otherwise disqualified to take part in school work (exclusive of those in the school infirmaries), and what provision the Local Government Board had made or intended to make for the reception, training, and protection of these children.—Mr. Chaplin replied that the managers of the Metropolitan Asylums District had made provision in their school at Darenth for imbecile children, and it was not improbable that some of the cases referred to might be sent to the school. There were no doubt other children whose mental condition was not such as to require their being sent to the Darenth school and for whom it would be desirable to make other provision. This question was an important one, and it was by no means limited to London, and he was not at present in a position to state what course it would be best to adopt. It must be borne in mind that there was some difference of opinion as to whether feeble-minded children might not be helped by association with children who were not similarly defective, and there were some persons who would be in favour of their being retained in the existing schools, special attention being given to their education and training.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ANDERSON, G. REINHARDT, F.R.C.S. Eng., L.R.C.S. Lond., has been appointed Honorary Medical Officer to the Southport Infirmary, vice the late H. D. McNicoll.

ARROL, CHAS., M.D. Glasg., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Borough of Queensborough.

BEHRENDT, M. R. J., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health by the Scunthorpe Urban District Council.

CAINE, N., M.B., C.M. Edin., has been appointed Junior House Surgeon to the Oldham Infirmary.

CLEGG, J. GRAY, M.D., B.S. Lond., F.R.C.S. Eng., &c., has been appointed Senior House Surgeon to the Manchester Royal Eye Hospital.

COOKSON, F., M.B. Lond., M.R.C.S., L.R.C.P. Eng., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

CROSS, W. F., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Evangelical Protestant Deaconesses' Institution and Training Hospital, South Tottenham.

DAY, E. J., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Dorchester.

DENING, EDWIN, L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer of Health for the Stowe-on-the-Wold Rural Sanitary District.

DEVANE, THOMAS FRANCIS, L.R.C.P.E., L.R.C.S.E., has been appointed Medical Officer to the Linen and Woollen Drapers' Institute for the Districts of Penge, Anerley, and Sydenham.

DURRANT, THOS. A., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health by the Market Harborough Urban District Council.

EDWARDS, ARNOLD J., M.D. Vict., B.Ch., has been appointed Honorary Surgeon to the Chorlton-upon-Medlock Dispensary, Manchester.

EVERS, CHAS. J., M.D. Durh., M.R.C.S., has been reappointed Medical Officer of Health for the Borough of Faversham and Port Sanitary Authority.

EYTON-JONES, THOMAS, L.S.A., has been appointed Medical Officer for the Ash Sanitary District of the Eastry Union.

FINDLAY, GEO., M.B., C.M. Aberd., has been appointed Medical Officer of Health for the Campden Urban Sanitary District.

GAYLOR, EDWARD, L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Alfreton Urban District Council.

GOULD, ALFRED PEARCE, M.B. Lond., F.R.C.S., has been appointed Surgeon to the Middlesex Hospital.

GRIFFITH, W. S., M.B. Camb., L.R.C.P. Lond., F.R.C.S., has been appointed Medical Officer of Health by the Milford Haven Urban District Council.

HALL, ALFRED, M.R.C.S., has been reappointed Medical Officer of Health for the Mayfield Rural Sanitary District.

HAMILTON, JOHN, M.D. Durh., L.R.C.P., F.R.C.S. Edin., has been reappointed Medical Officer of Health for the Swadlincote Urban Sanitary District.

Digitized by Google

HARRIS, S. O., L.F.P.S., L.M. Glasg., has been reappointed Medical Officer of Health for the Ely Urban Sanitary District.

HAYCROFT, C. H., M.R.C.S., has been reappointed Medical Officer of Health for the Sanitary District of Bow, Devon.

HERBERT, B. H., M.R.C.S., has been reappointed Medical Officer of Health by the Uttoxeter Rural District Council.

JELLY, GEORGE AUBREY, L.S.A., has been appointed Junior House Surgeon to the Macclesfield Infirmary.

JEPSON, E., M.D. Durh., M.R.C.S., has been appointed Honorary Physician to the Durham County Hospital.

KEYWORTH, A. F., L.R.C.P. Irel., M.R.C.S., has been reappointed Medical Officer of Health by the Marple Urban Sanitary Authority.

KIRBY, W. EGMONT, M.D. Brux., L.S.A., has been appointed Medical Electrician to the National Hospital for Diseases of the Heart and Paralysis, Soho-square.

LYDDON, RICHARD, M.R.C.S. Eng., L.S.A. Lond., has been appointed Surgeon and Agent to H.M. Coastguards for the Deal District, vice A. Bruce Payne, deceased.

MARSHALL, W. L. W., M.R.C.S., has been appointed Surgeon to the Huddersfield Infirmary.

MARTIN, SIDNEY, M.D., F.R.S., has been appointed Professor of Pathology in University College, London.

MENZIES, J. ACWORTH, M.D., C.M. Edin., has been appointed Junior House Surgeon to the Manchester Royal Eye Hospital.

MORRISON, C. S., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Superintendent of the County and City Asylum, Hereford, vice T. A. Chapman, retired.

MOYSEY, LEWIS, M.A., B.C. Cantab., has been appointed House Surgeon to the Paddington Green Children's Hospital.

MUDGE, THOS., M.R.C.S., has been appointed Medical Officer of Health for the Hayle Urban Sanitary District, vice J. Mudge, resigned.

NITCH-SMITH, R., M.R.C.S. Eng., L.R.C.P. Lond., has been reappointed Resident House Physician to the Westminster Hospital.

PATON, E. PERCY, M.D., M.S. Lond., F.R.C.S., has been appointed Surgical Registrar to the Westminster Hospital vice P. de Santi.

PURNELL, RICHARD, M.D. St. And., M.R.C.S., has been appointed Medical Officer of Health to the Wells Town Council.

RHODES, JAMES, M.R.C.S., has been appointed Medical Officer of Health for the Glossop Dale Rural Sanitary District.

RICHARDSON, H., L.S.A. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

RYALL, E. CANNY, L.R.C.P. Lond., has been appointed Curator of the Westminster Hospital Museum.

SELLERS, A. R., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Thornhill Urban Sanitary District.

SMITHIES, J. J., L.F.P.S. Glasg., L.R.C.P. Edin., has been reappointed Medical Officer of Health to the Bowland Rural District Council.

STEWART, J. H., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer of Health for the Borough of Lostwithiel.

SUTTON, JOHN BLAND, F.R.C.S. Eng., has been appointed Surgeon to In-patients at the Chelsea Hospital for Women.

SWAINSON, E. A. C., M.B. Camb., M.R.C.S. Eng., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

THOMPSON, PETER, M.B., Ch.B. Vict. has been appointed Senior Demonstrator in the Department of Anatomy at Owens College, Manchester, vice Arthur Robinson.

TROUP, J. MACDONALD, B.A. Cantab., L.S.A., has been appointed House Physician to the Paddington Green Children's Hospital.

VAWDREY, GEO., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer of Health to the Farnborough Town Council.

WALKER, E. G. A., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer of Health by the Wrotham Urban District Council.

YOUNG, ROBT., M.B., C.M. Aberd., has been appointed Medical Officer of Health for the Rochford Rural Sanitary District, vice G. D. Deeping, resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ABINGDON UNION.—Medical Officer for the Third District of the Union. The salary, £100 per annum, with certain articles, &c., provided by the Guardians. Applications to the Clerk, Union Offices, Abingdon.

BRIDGWATER INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

BRISTOL EYE HOSPITAL.—House Surgeon. Salary £60, with board and residence.

BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Assistant House Surgeon, for six months. On the satisfactory completion of that term an honorarium of 25 guineas will be granted. Also two Honorary Surgeons for In-patient Department.

CITY OF BIRMINGHAM.—Medical Superintendent for the City Hospital for Infectious Diseases, Little Bromwich, Birmingham, unmarried. Salary £200 per annum, rising by £20 per annum to £300 per annum, with apartments, rations, and attendance. Applications to the Town Clerk, Council House, Birmingham.

COUNTY ASYLUM, Dorchester.—Senior Assistant Medical Officer, unmarried. Salary £150, rising to £200.

HORTON INFIRMARY, Banbury.—House Surgeon and Dispenser. Salary £60 per annum, with board and lodging.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. Assistant Resident Medical Officer. Salary £50 per annum, with board and residence.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, Bloomsbury.—Resident Medical Superintendent, for one year. Salary £105 a year, with board and residence in the hospital. Also House Surgeon for six months, unmarried. Salary £20, with board and residence in the hospital.

HOSPITAL FOR WOMEN, Soho-square, London. — Assistant House Physician, for three months (non-resident).

LANCASHIRE COUNTY ASYLUM, Rainhill.—Assistant Medical Officer, for the summer months, as locum tenens. Salary, £2 2s. per week, with board and lodgings.

LONDON THROAT HOSPITAL, 204, Great Portland-street, W.—Non-resident House Surgeon, for six months. Salary at the rate of 25 guineas per annum.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, Soho-square, London, W.—Resident Medical Officer, for six months. Board, residence, laundry, and an honorarium of 10 guineas for that period.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—House Physician for six months. Salary at the rate of £60 per annum. Also Junior House Physician for six months. Board, lodging, and washing provided. Applications to the Secretary at the City Office, 27, Clement's-lane, Lombard-street, E.C.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Surgeon to Out-patients. Also Physician to Out-patients.

POPLAR HOSPITAL FOR ACCIDENTS, Blackwall, E —Assistant Resident House Surgeon. Salary £80 per annum, with board, lodging, and washing.

RANGOON MUNICIPALITY. — Health Officer. Salary Rs. 600 per mensem, rising to Rs.1000 per mensem by annual increments of Rs. 50 per mensem. Applications to Messrs. Ogilvy, Gillanders, and Co., Sun-court, 67, Cornhill, London, E.C.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, London.—Professors and Lecturers.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—House Physician, for six months. Salary at the rate of £40 per annum, with board, lodging, and laundry.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY, 60, King-street, Regent-street, London, W.—Surgeon.

STOCKPORT INFIRMARY.—Junior Assistant House Surgeon, for six months. Board and residence and an honorarium of £10 after six months' satisfactory services.

UNIVERSITY COURT OF ST. ANDREWS.—Lecturers.

VICTORIA CHILDREN'S HOSPITAL, Park-street, Hull.—Resident House Surgeon. Salary £50 per annum, with board and laundry.

WESTON-SUPER-MARE HOSPITAL AND DISPENSARY. — Medical Officer to the Provident Dispensary attached to the Hospital. Salary £80 per annum, with board, lodging, and washing.

Births, Marriages, and Deaths.

BIRTHS.

HILL.—On May 2nd, at Jasmine Cottage, Frognal, N.W., the wife of Leonard Hill, M.B. Lond., of a son.

LATTER.—On May 6th, at Earl's-avenue, Folkestone, the wife of Cecil Latter, M.D., B.C. Cantab., of a son.

MUSSEN.—On May 6th, at Welford-road, Leicester, the wife of W. Mussen, L.R.C.P. Eng., of a daughter.

SHADWELL.—On May 11th, at Lynhurst, Walthamstow, the wife of St. Clair B. Shadwell, M.D. St. And., of a daughter.

STEPHENSON.—On May 8th, at Welbeck-street, the wife of Sidney Stephenson, M.B. Edin., of a daughter.

VACHELL.—On May 11th, at Charles-street, Cardiff, the wife of Charles Tanfield Vachell, M.D., of a daughter.

WOORE.—On May 8th, at Strathallan, Upper Norwood, the wife of Frank Woore, late Staff Surgeon, R.N., of a daughter.

MARRIAGES.

BLAKE—HARRIS.—On May 11th, at the City Temple, Victor John Blake, M.B., B.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., of Elsinore, Ventnor, I. of W., to Amy Katharine Harris, eldest daughter of B. Harris, of Wrexham.

THOMSON—DOUGLAS.—On May 7th, at Algiers, William Thomson, M.D. Edin., to Clara Douglas, daughter of the late W. Douglas, of Ilkley Hall, Yorkshire.

DEATHS.

BALL.—On May 10th, at Croxby House, Hounslow, William Montague Ball, M.B. Aberd., aged 41.

COOPER.—On May 7th, at 106, Gower-street, W.C., in her 31st year, Vernon, *née* Wilkinson, formerly of the nursing staff of Charing-cross Hospital, wife of Ernest Frederick Cooper, M.R.C.S., late of 10, Belsize-road, N.W.

MCCREADY.—On May 6th, at the Glebe, Ballynahinch, Ireland, the Rev. Edward McConkey McCready, A.B., M.B. Dubl., aged 67 years.

MOXEY.—On May 8th, at Paris, David Anderson Moxey, M.D., M.R.C.P. Lond., Fulton Lecturer on Elocution, New College, Edinburgh.

STATTER.—On May 9th, at Snapethorpe Hall, near Wakefield, William Statter, J.P., F.R.C.S., in his 90th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.).

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Great Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.). St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.) Gt. Northern Central (2.30 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (18th).—VICTORIA INSTITUTE (8, Adelphi-terrace, Strand).—4.30 P.M. A Paper on Climate in Egypt in Geological, Prehistoric, and Ancient Historic Times, by H.E. Grant Bey, will be read by Dr. D. Macgregor.

SOCIETY OF ARTS.—8 P.M. Mr. J. Swinburne: Applied Electro-Chemistry. (Cantor Lecture.)

MEDICAL SOCIETY OF LONDON.—Annual Conversazione.—8.30 P.M. Oration: Dr. W. H. Allchin: The Breaking Strain.

TUESDAY (19th).—PATHOLOGICAL SOCIETY OF LONDON.—Papers: Mr. Thorburn (Manchester) and Mr. Westmacott (Manchester): On Hypertrophic Pulmonary Osteo-arthropathy.—Dr. Fielder: Osteitis Deformans.—Mr. Edmunds: Thyroid Body in Graves's Disease.—Dr. N. Moore: Growth of Transverse Colon. Card Specimens: Dr. Tyson (Folkestone): Elongated Appendix with Calculus.—Mr. Shattock: Cultured Variation in Streptococcus Pyogenes Bovis.—Dr. Seligmann: Streptothrix Maduræ.—Mr. J. Smith: Filariæ from Lymph Scrotum.—Dr. Rolleston: (1) Mediastinal Growth from Thymus: (2) Large Cyst in Carcinoma Mammæ.—Dr. Hawkins: (1) Perforation of Gall Bladder in Enterica; (2) Horseshoe Kidney.

SOCIETY OF ARTS.—8 P.M. Mr. G. Simonds: Bronze Casting in Europe.

WEDNESDAY (20th).—DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.)—4.45 P.M. Annual Meeting and Conference. Election of Officers. Introductory Address by President. Paper: Dr. W. G. Smith (Dublin): Notes upon Chrysorobin and Chrysophanic Acid.—5.45 P.M. Cases.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover-sq., W.).—8 P.M. Meeting.

SOCIETY OF ARTS.—8 P.M. Capt. W. de W. Abney: Orthochromatic Photography.

FRIDAY (22nd).—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Annual General Meeting. Election of Officers for Session 1896-1897. Dr. Clemow: A Case of Typhoid Fever with Hyperpyrexia and Cardiac Dilatation; Venesection; Recovery.—Dr. Rolleston and Mr. Haward: A Case of Chronic Dilatation of the Colon.—Mr. W. G. Spencer: Punctured Wound of Right Ventricle of Heart through Second Left Intercostal Space, severe Primary and three Secondary Hæmorrhages, Healing of the Wound, subsequent Post-mortem Examination after Death from Disease.—Mr. G. R. Baldwin: A Case of Central Sarcoma of the Femur with Early Dissemination.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (18th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. Woakes: Ear Disease during Dentition and the Exanthemata.

WEDNESDAY (20th).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Dr. Ormerod: Friedreich's Ataxia.

HOSPITAL FOR CONSUMPTION, &c. (Brompton):—4 P.M. Mr. Godlee: Bone and Joint Disease associated with Chest Affections.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Herpes and Allied Diseases.

THURSDAY (21st).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Qualitative Tests for Albumins.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. J. Hutchinson: Clinical Lecture.

VICTORIA HOSPITAL FOR CHILDREN (Tite-street, S.W.).—4 P.M. Dr. M. Murray: Selected Medical Cases.

FRIDAY (22nd).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Anthrax and Malignant Œdema.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. Holloway: Anæsthetics, as employed in the practice of the Hospital.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"THE DOOM OF THE SILKWORM."

MR. THOMAS CHRISTY, of 25, Lime-street, referring to the annotation in THE LANCET of May 9th, encloses us a few observations by a prominent member of the silk trade. He says that silk made from wood as described in the *Times* is no novelty, a factory having existed for some years at Besançon for producing this article, but the French, he adds, have up to the present discovered little use for it, much money having been lost at this factory. Again, he says: "Lyons manufactories have not used the article because it is scarcely any cheaper than raw silk owing to the expense of the solvents used in its production. So far the only market where it has been used is St. Chamoud, where it has been employed in the production of braids. The quantity, however, used in France at the present time is not more than 150 to 200 kilos per week. The great objection to the use of artificial silk is if wetted after being woven it tears like paper, and it cannot be charged or weighted in the dye as raw silk." With this communication we have received a sample of artificial silk. We do not find it to be specially inflammable; indeed, it does not burn with the rapidity and energy of a nitro-compound. This is not surprising when, as we have already stated, the product is denitrated by means of ammonium sulphide before it is finished. While we are not able to confirm the statement that when wet it tears like paper, yet under this condition it is certainly more easily torn than natural silk is. It should be remarked that natural silk requires care, which most people scrupulously take, to preserve it from the deteriorating influences of wet. We may add that although the *Times* devoted considerable space to the description of this process, yet it has formed the theme of many excellent papers contributed to the Society of Chemical Industry by Mr. Cross and Mr. Bevan, the last paper having been read so recently as Monday, the 4th inst.

Dr. J. D. M.—We think that B. would do well to take the fee. It is clear that he ought to be paid for his services. The payment ought to have come from P., but it is not B.'s fault that it will have a different origin.

"WANTED, A SUGGESTION FOR TREATMENT."

To the Editors of THE LANCET.

SIRS,—In answer to "Puzzled" asking for suggestions as to treatment of warts on the face I would recommend him to try five minims of Fowler's solution three times a day and continue for a lengthened period. I am, Sirs, yours truly,

South Hampstead, N.W., May 9th, 1896. MACADAM GREGOR.

To the Editors of THE LANCET.

SIRS,—Your correspondent may have mistaken sycosis for verrucæ. When I was house surgeon at the London Lock Hospital Mr. Berkeley Hill's favourite remedy was exsiccated (caustic) sulphate of zinc. I should advise sulphur sublimatum, one of the best and safest dusting powders in the case in question, to be applied as a strong ointment with lanoline at night, and cleansed off in the morning with crumb of bread poultice for an hour or more, then dusted with sulphur rice starch, 1 in 50, or SO_2 (B.P.) to commence with, and applied, diluted, three or four times a day. I am, Sirs, yours truly,

Fleetwood, May 12th, 1896. W. G. TILEY, M.R.C.S. Eng.

Omega.—We do not answer such questions.

"AN INSURANCE COMPANY AND A MEDICAL REFEREE."

WE have received from the manager of the insurance company to which we alluded under this heading in THE LANCET of May 2nd a communication commenting upon our account of the matter. The manager asserts that Dr. Bontor was offered 7*s.* 6*d.* in the beginning and not 5*s.* and that that gentleman had an opportunity of declining to make the examination. "The scale of fees," says the manager, "has been determined upon by leading members of the medical profession; and from time immemorial life offices have paid one fee for small policies and one for large."

MR. LEET'S PAMPHLET ON DAIRY MILK: ITS DANGERS AND THE REMEDIES, WITH THE OPINIONS OF TWENTY EMINENT BRITISH PHYSICIANS UPON STERILISED MILK FOR INFANT FEEDING.

To the Editors of THE LANCET.

SIRS,—Sir Dyce Duckworth, physician to St. Bartholomew's Hospital, London, writes to me thus on the 2nd inst.: "I must request you to write to THE LANCET and the *British Medical Journal* to the effect that you have unwarrantably published some remarks of mine in your pamphlet without my permission, remarks taken from a private letter in reply to a simple inquiry on your part."

The following cutting from page 23 contains the passage alluded to by Sir Dyce Duckworth:

"APPENDIX.

"OPINIONS OF TWENTY EMINENT BRITISH PHYSICIANS UPON THE SUBJECT OF STERILISED MILK FOR INFANTS.

"1.—Sir Dyce Duckworth, Physician to St. Bartholomew's, London:—'There is an excellent form of Milk Steriliser, known as Professor Soxhlet's. There are now one or two Milk Companies here which send out Sterilised Milk daily at 5*d.* per quart. The working of the steriliser is very simple, and the advantages very great. If you do not know it I would advise you to read Sir W. Priestley's address on the subject, *British Medical Journal*, December 7th, 1895.'"

Then follow the opinions of eighteen other physicians. From the last page of the pamphlet the following cutting will explain the reason why it was published.

"N.B.—These valuable 'Opinions,' chiefly brief replies on the post-cards enclosed to each of these eminent medical men, politely requesting the name of the Milk Steriliser they recommend, are now published upon the grounds of the 'present distress,' when the purveyor of 'Dairy Milk' can defy the laws and poison hundreds of British children by the dirty, diseased, and watered compound he dares to call 'Fresh New Milk.' Is the family physician to look on at all this and take fees for prescribing physic that does not, cannot, kill the poisonous Milk?"

The question of professional ethics was inadvertently forgotten in the anxiety to make known to "nurses and mothers" (to whom the pamphlet has been dedicated) some hitherto unpublished advantages in the treatment of sick children, and of adults with gastric troubles, from the use of a cooler for hot sterilised milk—a simple tin pan apparatus, furnished with inlet and outlet pipes for running water from the house main tap, in which can be immersed any milk steriliser, and in some five minutes the milk temperature be reduced over 50°, the burnt taste of cooked milk avoided, no scum coagulation on its surface, and post-scalding microbic contamination held in check more simply and inexpensively than I have otherwise seen described. Having given daily personal attention to this subject in our private medical home for twelve months I trust my explanation and apology will be accepted by Sir Dyce Duckworth and by any of the other eighteen physicians should they object to their opinions having been published in the pamphlet.

I am, Sirs, yours truly,

CHARLES H. LEET, F.R.C.S. Eng.,

Waterloo, Liverpool, May 7th, 1896. Late Surgeon-Major A.M.S.

Etiquette is referred to an answer to "M.R.C.S." Attendance upon such a club in no way contravenes the dignity of the profession.

"A NOVEL METHOD OF INTRODUCING A NEWLY-QUALIFIED MAN."

To the Editors of THE LANCET.

SIRS,—Thank you for sending me THE LANCET containing the letter of "Vindicator." The plate was an ordinary brass plate with name only; on another small plate—not wood and about the size of a sheet of foolscap—the hours of attendance, &c., were given. A copy is appended for your perusal and judgment. Owing to correspondence in connexion with an appointment (correspondence enclosed) it was known to all the inhabitants that J—— was up for his final examination at Edinburgh on April 13th, and "Vindicator," as a medical man, would know that the examinations terminated on Friday, April 17th. Reports were disseminated on the same Friday night and the following morning that J—— had failed to pass the examination, and were so industriously circulated that within twenty-four hours every one in the place was certain they were true. After the false gossip had full swing the truth of J——'s success became known. The villagers, after their own fashion, employed the crier to strangle the lie as soon after its birth as possible; but of all this poor J—— at Edinburgh and his father eight miles off were as innocent as the Editors of THE LANCET, nor did they have any intimation of what took place until the Tuesday following, when three days had elapsed. It seems too absurd to have to repudiate or disavow such ridiculous proceedings, in which J—— and those responsible for him took no act or part, and were guilty of no fault either of commission or omission, but if such be deemed necessary it is hereby emphatically repudiated. I am, Sirs, yours faithfully,

May 4th, 1896. VERACITY.

*** Neither Dr. J—— nor his friends can be held responsible for the spontaneous action of the villagers, and we are glad to print this satisfactory explanation. The legend on the brass plate is not offensive. THE LANCET was not sent from this office to "Veracity", the highly contentious conclusion to whose letter has no bearing on the case and has therefore been omitted.—ED. L.

M.R.C.S.—It is preferable that a medical man's business should not be interfered with by a lay committee; but our correspondent's appointment otherwise seems unobjectionable. The fact that he examines all new candidates as to their physical and pecuniary conditions before admitting them to the benefits of the association is a very important one, for he is able to guard his services from gross abuse.

THE WRIGHT DEFENCH FUND.

To the Editors of THE LANCET.

SIRS,—The following additional subscriptions have been promised or received for the above fund since your issue of May 9th:—

Mr. J. B. Stuart, J.P., F.R.C.S.Ed. (Wigan) ...	1	1	0	Mr. J. G. Dunn (Preston)	10	0	
Mr. Thomas Jones, F.R.C.S. Eng. (Manchester)	3	3	0	Dr. G. B. Barron, J.P., (Southport)	10	6	
Mr. T. Brayton (Hindley)	1	1	0	Dr. Benson (Wigan), additional	10	6	
Mr. Bentham (Abram) ...	1	1	0	Mr. Barnes (Bolton)	5	0	
				Previous List	30	17	0

As £150 is required the committee will be pleased to receive further subscriptions, but are desirous to close the list by June 1st. Thanking you for your previous insertion of the appeal.

I am, Sirs, yours truly,

Wigan, May 13th, 1896. WM. BERRY.

Dr. John McClymont is thanked for his communication. There are practical reasons why it would not be politic to print this at the present moment, but later we may notice the point.

One of the Profession.—The cases are not of sufficient frequency, we are thankful to say, to make any drastic methods of remedy widely called for.

An Interested Layman should consult his regular medical attendant.

During the week marked copies of the following newspapers have been received:—*Craven Herald, Hereford Times, Somerset County Herald, Hampshire Telegraph, Cheltenham Mercury, North British Agriculturist, Cornishman, Standard, Elgin Courant, Eochdale Observer, Wakefield Herald, Midland Free Press, Glasgow Herald, South Wales Daily News, Northern Whig, Leicester Post, Yorkshire Herald, Manchester Guardian, Derby Express, Birmingham Post, Newcastle Leader, Harrogate Advertiser, Worcestershire Chronicle, Preston Herald, Retford News, Eastern Daily News, Liverpool Daily Post, Carlisle Journal, Scotsman, Dover Express, Jackson's Oxford Journal, Leeds Mercury, Sussex Daily News, Blackpool Gazette, East Essex Times, Cambridge Express, Yorkshire Post, Royal Cornwall Gazette, Sheffield Independent, Bristol Mercury, Architect, Times of India, Local Government Chronicle, Builder, Pioneer Mail, Weekly Free Press and Aberdeen Herald, Christian World, Lincolnshire Echo, Reading Mercury, Citizen, Hertfordshire Mercury, Mining Journal, City Press, Rossendale Gazette, Kilrush Herald, Leitrim Observer, West Middlesex Standard, Guy's Hospital Gazette, Local Government Journal, Gloucestershire Chronicle, Surrey Advertiser, Montreal Daily Star, Isle of Ely Advertiser, Ulverston Advertiser, Shrewsbury Chronicle, Times (Philadelphia), North Eastern Daily Gazette, Clevedon Mercury, Pall Mall Gazette, Devon and Exeter Gazette, &c., &c.*

The Arris and Gale Lectures

ON THE

PHYSIOLOGICAL FACTORS INVOLVED IN THE CAUSATION OF DROPSY.

Delivered before the Royal College of Surgeons of England on Feb. 17th, 19th, and 21st, 1896,

BY ERNEST H. STARLING,
M.D. LOND., M.R.C.P.,
JOINT LECTURER ON PHYSIOLOGY AT GUY'S HOSPITAL.

LECTURE III.[1]

THE CAUSATION OF DROPSY.

MR. PRESIDENT AND GENTLEMEN,—Having in the two preceding lectures given a sketch of the working in the normal animal of the processes of lymph-production and lymph-absorption, I wish now to point out briefly the deviations in these processes which are found in the various pathological conditions associated with dropsy and which are responsible for the production of the dropsy. For the better understanding of this question I have drawn up a table of the various changes in the normal conditions of the body which will bring about, or help to bring about, an abnormal distension of the connective tissue spaces with lymph. In this table the changes which are the most important for the production of dropsy are italicised.

FACTORS INVOLVED IN THE CAUSATION OF DROPSY.

I.—Factors causing increased transudation:—
- A. *Increased intra-capillary pressure:—*
  - *a. Venous obstruction.*
  - *b.* Vasodilatation.
  - *c.* Plethora.
- B. *Increased permeability of vessel wall:—*
  - *a. Local injury* by mechanical irritants.
  - ,, ,, ,, thermal ,,
  - ,, ,, ,, chemical ,,
  - *b. Malnutrition.*
  - *c. General injury by circulating poisons (?).*
- C. Watery condition of blood (hydræmia).

II.—Factors causing *diminished absorption:—*
- A. By lymphatics:—
  - *a.* Paralysis of limbs.
  - *b.* Obstruction of lymphatic trunks.
- B. By veins:—
  - *a.* Venous obstruction.
  - *b.* Watery condition of blood.
  - *c.* Concentrated transudations.

It is important to remember that probably under no circumstances can dropsy be ascribed to an abnormal change in one of these processes. This, however, can also be said of any other diseased condition of the body. We know that the organism responds to a destruction of a considerable part of the excretory apparatus of the kidney by sending up the general blood-pressure, and so driving an increased amount of blood through the still healthy glomeruli. We cannot thus say that two-thirds of the kidneys are practically inactive under normal conditions because excision of two-thirds causes no change in the general condition of the animal or any appreciable heaping up of urea in the blood. In the same way we find that the organism has various powers of accommodating itself to changed conditions in its lymphatic apparatus, so that it is in most situations difficult to upset the normal balance—i.e., cause dropsy—by altering only one of these factors, unless the alteration be of a very extreme degree. In nearly all cases we shall find that the dropsy is due to the simultaneous alteration of two or more of these factors. In the following lecture I shall try to show, so far as our imperfect experimental knowledge allows, which of these factors are affected in the chief forms of dropsy known clinically, and also to show how the normal balance between production and absorption has been in each case upset.

The form of dropsy which is simplest in its pathology is that which is due to venous obstruction. Clinically one meets with dropsy of one extremity due to obstruction of the veins draining that part, either in consequence of pressure by growths or of thrombosis occurring in the vein itself. It would be natural to ascribe this dropsy to the increased lymph-production consequent on the raised intra-capillary pressure behind the obstruction. On investigating the subject experimentally, however, one finds that the causation is not quite so simple. Here, as in nearly all other cases, more than one factor is at work. It is a well-known fact that although obstruction of the femoral vein by a thrombus will give rise to pronounced œdema of the leg, yet ligature of the femoral vein in a healthy man may have no ill-effects whatever. On investigating the subject experimentally we find that ligature of the femoral vein, or even of the lower end of the inferior vena cava, in dogs produces no œdema of the legs. We can, however, produce an œdema if we raise the intra-capillary pressure still higher than in these experiments. Paschutin showed that ligature of all the venous trunks of the dog's leg caused œdema of the foot and ankle. Ranvier has shown that if, after ligature of the inferior vena cava, the sciatic nerve be divided on one side so as to produce dilatation of arterioles on that side, the limb in which the nerve has been divided will become œdematous. Cohnheim has shown that œdema may be brought about by injecting the veins of the leg with plaster-of-Paris. We see, then, that we can produce œdema in a limb provided we raise the intra-capillary pressure to a sufficiently high point. If only one or two veins be obstructed the outflow by the collateral circulation is sufficient in a healthy animal to ward off any œdema. If the lymph be collected by placing a cannula in one of the lymphatics of the leg it will be observed that after these severe obstructions it becomes red from the presence of red blood-corpuscles. In my first lecture I mentioned that the presence of a quantity of red blood-corpuscles in the lymph showed that the rise of intra-capillary blood-pressure was, so to speak, hyperphysiological, and that one could obtain a very definite increase in the lymph-flow without the appearance of any red blood-corpuscles by raising the intra-capillary blood-pressure to a somewhat less degree. Why, then, do we not obtain œdema of the dog's leg by a simple ligature of the vena cava or femoral vein? In man we know that obstruction of either of these two vessels frequently brings about œdema of the lower extremities and that the œdema fluid present in the interstices of the tissues is colourless and free from red blood-corpuscles—i.e., corresponds to the lymph of moderate venous obstruction. The apparent discrepancy which is found here between clinical observations and the results of experiment depends on the fact which I have emphasised at the beginning of this lecture—viz., that it is impossible to upset the physiological balance, which prevents the occurrence of dropsy, by a moderate disturbance of either of the factors, lymph-production or lymph-absorption. Such an enormous rise of capillary pressure as is produced by filling all the veins of the leg with plaster-of-Paris probably rarely or never occurs under clinical conditions. The occurrence of dropsy in man in consequence of venous obstruction is nearly always due to the simultaneous working of two or more factors. We have therefore to decide, in the first place, why in a healthy animal with a moderate venous obstruction no œdema is produced; and, secondly, what are the subsidiary factors which in man combine with the venous obstruction to bring about an œdema.

In considering the first point, it is essential to remember that in the case of œdema of the limbs we are dealing with the most impermeable capillaries in the body, so that under normal conditions a considerable capillary pressure is required to separate the lymph from the blood, and the lymph so separated has lost the greater part of its proteid. I have already shown how, in consequence of this difference of composition between plasma and lymph, there is an accurate balance between the force tending to produce exudation—i.e., the capillary pressure, and the force tending to produce absorption—i.e., the difference of osmotic pressures between blood plasma and lymph. Now if in a normal animal a vein be obstructed the first effect is a rise of capillary pressure and increased exudation. Since, however, in the affected capillaries and veins the onward flow of blood is checked, the increased exudation must be at the expense of

[1] Lectures I. and II. were published in THE LANCET of May 9th and 16th, 1896, respectively.

Digitized by Google

an increased concentration of the blood plasma. This increase in concentration must cause an increase in the difference between the osmotic pressures of plasma and lymph and the absorbing force—i.e., the osmotic pressure of the plasma—will rise until it is equal to the driving-out force—i.e., the capillary pressure. In a normal dog with normal vessels the processes tending to cause œdema will be pulled up almost as soon as they have started, and no œdema will result from moderate venous congestion. It is easy now to see how we might cause œdema by venous congestion. In the normal animal the factor which restrains the appearance of œdema is the impermeability of the vessel wall, since it is this impermeability which maintains the difference in osmotic pressure between blood and lymph. If, therefore, we can increase the permeability in any way the balance of processes will be lost, exudation will predominate over absorption, and œdema will result. In my first lecture I mentioned to you several methods by which the permeability of the capillaries might be increased, with increased lymph-formation as the result. A much more trifling change in the vessel-wall than is produced by the agents mentioned in that lecture will suffice to cause marked effects on lymph-production where the intra-capillary pressure is considerably raised by venous congestion. Now it must be remembered that the capillary wall is alive and is composed of cells which have a metabolism of their own, and which, like all other cells of the body, are dependent for their proper nutrition on a free supply of oxygen and nutrient material and a free exit for their waste products. Their only function, so far as we know, is the maintenance of their integrity as a membrane with certain properties differing according to the region of the body in which they happen to be situated. If they are injured in any way the resistance of the membrane is diminished and its permeability is increased. Such an injury will follow if they be deprived for some time of fresh supply of nutrient material and oxygen. Cohnheim showed that after long-continued anæmia of the rabbit's ear the vessels became so permeable that the restoration of the normal circulation was followed by pronounced œdema of all the tissues. If the anæmia be of shorter duration no œdema is caused by restoration of the normal circulation, but can be called forth at once by ligaturing the principal vein draining the part. Now a long-continued venous obstruction must affect the vessel-walls in the same way as anæmia, since here also the cells will be starved or asphyxiated. Hence it is that in the chronic conditions which give rise to venous obstruction in man we have the production of œdema. Moreover, in the cases in man in which we obtain dropsy as the result of venous obstruction there are generally other conditions present which tend to damage the vessel-wall and so increase its permeability. Thus the mere occurrence of thrombosis points to a probable diminution of nutrition of the vascular endothelium, and occurs most frequently in patients suffering from anæmia or allied changes in the blood. The occurrence of malignant growths in the neighbourhood of a vein is, moreover, usually associated with a condition of cachexia, and therefore with an impoverished blood-supply to the endothelium. Now we have experimental evidence that the circulation of watery blood through the vessels, if continued for some length of time, alters the vessel-wall to such an extent that a moderate venous obstruction will produce œdema. I have already mentioned that ligature of the femoral vein in a healthy dog causes no œdema. Cohnheim has shown that if the dog be first rendered hydræmic by bleeding repeatedly at intervals of a few days ligature of the femoral vein will then be followed by œdema. It must be remembered that in this case we have still a third factor which helps in the production of œdema. There is no doubt that a more watery plasma will filter more easily through the vessel-wall, and the diminution of proteids in the plasma must be accompanied by a diminution of the osmotic pressure in the plasma, which is active in absorption. To sum up, we may say that œdema can never be brought about in the limbs by a moderate rise of venous pressure, provided that the capillaries retain their normal impermeability. Œdema will occur as soon as the permeability of the vessels is increased. The injury leading to this increase in permeability may be brought about in any of the following ways: (1) long-continued venous congestion (asphyxia of cells); (2) an excessive rise of intra-capillary pressure breaking down the normal resistance of the cells; and (3) mal-nutrition due to an impoverished state of the blood.

There is one method of producing œdema experimentally about which I must say a few words. Wooldridge showed that if a femoral vein in the dog be ligatured and a solution of tissue fibrinogen then injected, a considerable dropsy of the leg was produced, provided the dog survived the experiment. He ascribed this effect to the production of a disturbed relationship between the blood and the vascular wall. Now it is important to remember that the presence of fibrinogen in the blood has very little importance for the production of lymph. If we "kill" the blood by defibrinating it several times and reinjecting it, the lymph-flow from the thoracic duct remains unaltered. In this experiment of Wooldridge we have a concurrence of several factors. The most important of these is the occurrence of thrombosis in the veins of the leg, and this thrombosis is due, as Wright showed, to the fact that venous obstruction causes a heaping up of CO_2 in the blood, and therefore an increased susceptibility to the effects of tissue-fibrinogen. In repeating this experiment I have always found that the veins in the œdematous parts of the leg were thrombosed, and I am, therefore, inclined to look upon this experiment as very nearly analogous to Cohnheim's plaster-of-Paris experiment. We probably at the same time have an increased permeability of the vessels due to the poison injected, but that this direct action of the poison on the filtering membrane is of subsidiary importance is shown by the fact that if we inject the tissue-fibrinogen into a dog whose blood is defibrinated, so obviating the intravascular clotting, we escape at the same time the production of any œdema.

Much more frequent than the œdema due to local venous obstruction is the œdema which occurs as a consequence of uncompensated or imperfectly compensated heart disease. In this class of cases we have much more complicated conditions than in the class I have just discussed. The œdema of heart disease is generally looked upon as obviously due to a rise in venous pressure and consequent venous obstruction. Taking the existence of a high venous pressure in such cases as a fact, we have to inquire into the causes for this rise of pressure and whether this rise of pressure will extend to the capillaries. To investigate the causation of the dropsy in heart disease, therefore, we must first take into account the alterations in the circulation as well as the alterations in the absorption and production of lymph. The vascular system in an animal can be looked upon as a closed system of tubes having a definite capacity. If the circulation were brought to a standstill the pressures at all parts of the system would become the same. This pressure is called the mean systemic pressure, and in a dog is equal to about 10 mm. Hg. Now in such a system it is evident that the height of this mean pressure depends solely on the relation between the amount of contained fluid and the capacity of the system. If circulation be established by means of the heart's beat, the relation between the capacity and the volume of blood remaining unchanged, no alteration can occur in the mean pressure. All we have is an alteration in the distribution of the pressure. Behind the heart—that is to say, on its venous side—the pressure will sink below the mean systemic pressure; on the arterial side the pressure will be raised above the mean pressure. If after the establishment of the circulation the action of the heart pump be interfered with, as by damage to the valves, or be checked altogether, the pressures on each side will tend to return to the zero of the system—i.e., the mean systemic pressure. There will therefore be a fall of arterial pressure and a rise of venous pressure to this point. It becomes important, therefore, to know at what point in the system the pressure, while the circulation is going on, is equal to the mean systemic pressure. We find by experiment that this turning point of the circulation, so to speak, is situated in the region of the hepatic capillaries, in the abdomen, and about the level of Poupart's ligament in the femoral vein. Failure of the heart pump would therefore cause a rise of pressure in the vena cava and in the large veins of the neck, but a fall of pressure in the portal vein, in the peripheral veins of the legs, as well as in the arteries. It would seem, therefore, that failure of the heart's action, to whatever cause it may be due, can only bring about a fall of pressure in the capillaries of the intestines and peripheral parts of the body. How is it, then, that in morbus cordis we obtain such distinct signs of raised venous pressure in the peripheral parts of the body? The clue to this difficulty is, I believe, to be found in the fact that all cases of uncompensated cardiac lesions are associated with hydræmic plethora. This association has been shown actually to exist by the observations of Stintzing and Gumprecht. I wish, however, to show you how such a condition of hydræmic plethora must be

Digitized by Google

an inevitable physiological consequence of the failure of the heart pump. We have just seen that heart failure causes a fall of pressure on both sides of the intestinal capillaries and limb capillaries, so that the first effect on these capillaries must be a fall of pressure. This fall of pressure, like that consequent on artificial anæmia, will disturb the relationship between the blood and the lymph; there will be an absorption of lymph from the tissue spaces, the blood will be increased in volume, and there will be, therefore, a certain rise of the mean systemic pressure and a shifting of the neutral point towards the periphery. The first effect of heart disease on the limbs will thus be to make them less full of lymph than they normally are, and a new condition of equilibrium will be established between the capillary pressure and the lymph absorption. This sucking of fluid from the tissues will affect also the alimentary canal. The extreme thirst—i.e., the increased absorption of fluid from the alimentary canal—which follows loss of blood is a familiar phenomenon. Now this increased absorption of fluid from the alimentary canal will tend to continue until the pressure in the capillaries of the mucous membrane is restored to its normal height. We have, therefore, as the effect of heart failure an initial absorption of fluid from the connective tissues of the limbs and a continued absorption of fluid from the alimentary canal. At the same time, in consequence of the low arterial pressure, the loss of fluid to the body by way of the kidneys is diminished. The result of these last two factors is to cause a continual increase in the amount of circulating fluid—an increase which must theoretically go on until the capillary pressures in the intestines and kidneys are restored to their normal heights. The ultimate result of heart failure is a condition of hydræmic plethora and, therefore, a raising of the mean systemic pressure above its normal height. With the ever-growing balance in favour of absorption of fluid into the bloodvessels the rise of venous pressure extends further and further towards the periphery until the rise affects also the capillary pressure, and in all dependent parts of the body exudation predominates over absorption. The effect of this continued absorption is that the over-full veins present more and more blood to the heart—the heart which was unable to send onwards into the arteries even its normal quantity. It is evident that here we have a vicious circle of events tending to the death of the animal. If, however, the animal be freed from the normal struggle for existence the heart may be able to empty itself and so gradually undergo hypertrophy, and the cardiac disease may be compensated.

It is probable that in the production of the œdema of heart disease we have a concurrence of the same subsidiary factors as were mentioned when dealing with the subject of venous obstruction. In consequence of the failing circulation there is a stagnation of blood in the vessels, and the oxygenation and nutrition of the capillary walls cannot be normally carried out, so that their permeability is increased. We have here, moreover, a factor which was not present in simple venous obstruction—viz., an obstruction to the outflow by the lymphatics in consequence of the raised venous pressure at the opening of the thoracic duct. We see, then, that the production of dropsy in heart disease is by no means so simple as it at first appears, but that it is due to a complicated series of interacting mechanisms, all of which tend to the death of the organism. We may sum up the sequence of events which ensue on failure of compensation as follows:—Stage 1.—Heart-pump failure; fall of arterial pressure; rise of pressure in the venous trunks near the heart; fall of capillary pressures in the peripheral parts of the body, in the kidneys, and in the intestine; and absorption of fluid by bloodvessels from intestines and peripheral tissues. Stage 2.—Continued absorption from the alimentary canal with diminished excretion from the kidneys, and production of hydræmic plethora with rise of mean systemic pressure. This leads to Stage 3—rise of capillary pressure in all dependent parts of the body, capillaries injured by malnutrition, and excessive transudation, leading to dropsy. Stage 4.—The continued hydræmic plethora leads to ever-increasing over-filling of the heart cavities and to ultimate failure of the already incompetent heart.

I have already described to you Wooldridge's experiment on the production of œdema by the injection of tissue fibrinogen. This observer ascribed the dropsy of heart disease chiefly to an auto-intoxication of the organism by the fibrinogens contained in its lymph. Now it is apparent that the enormous rise of pressure in the liver in heart disease, which is instanced by the swelling and pulsation of this organ, must give rise to a greatly increased flow of lymph from the thoracic duct into the blood, so that we have the conditions present which are necessary for this auto-intoxication to take place. It is possible that there may be a certain amount of poisoning of the organism effected in this way, but in the light of my experiments, which I described to you recently, I do not think that this auto-intoxication can be looked upon as at any rate the chief factor in the production of the dropsy. I believe that careful experimental investigation will show that the production of the dropsy can be perfectly explained by an upset of the balance between the physical conditions which normally control filtration from, and absorption by, the bloodvessels in different regions of the body.

In these two classes of dropsy the primary factor is an alteration in the mechanical conditions of the circulation, bringing about a rise of capillary pressure and increased exudation in the part affected. In the next class with which we have to deal the primary change affects, not the intra-capillary pressure, but the vessel-wall. A change of the filtering membrane is thus produced, so that it becomes more permeable and allows, under normal capillary pressures, an excessive exudation, and the exudation is richer in proteids than is the normal lymph of the region in question. Since an alteration of the vessel-wall is one of the main features of inflammation Cohnheim has classed all œdemas in which the primary affection is that of the vessel-wall as inflammatory œdemas. In my first lecture I pointed out various means by which the permeability of the capillary wall might be increased, and showed how, under these circumstances, the limb capillaries might be reduced to the condition of liver capillaries. Here, as in all other cases in which œdema occurs, we have more than one factor at work. The capillary pressure of the part remaining at its normal height, the increased permeability allows of a largely increased exudation—there is increased lymph-production. The lymph, however, contains more proteids than normal, so that the difference of osmotic pressure between it and the circulating plasma is diminished, thereby causing a diminution of the absorbing force. In all cases of inflammatory œdema these two factors are at work concurrently—increased production and diminished absorption. This alteration of the vessel-wall may be brought about in two ways: either by the application of injurious agents to the vessels of any given part or by the introduction of poisonous substances into the blood-stream. Thus a local alteration of the vessel-wall may be caused by application of mechanical violence, crushing the tissues. It is possible that in this case we have at work, not only the direct result of the injury on the vessel-wall, but also a secondary injury of the capillaries in consequence of the development of poisonous products of disintegration in the bruised tissues surrounding the capillaries—e.g., tissue fibrinogens. We can produce the same change by exposing the tissues for a few minutes to a temperature of over 50° C. or by depriving them for some time of the normal blood-flow. All the local œdemas produced by inoculation of chemical or microbic poisons at the point of inoculation are of this nature. The swelling produced by the sting of a bee or by the inoculation of anthrax is due to the deleterious effects of the poison injected on the capillary walls at the point of inoculation. Metchnikoff has shown that the emigration of white blood-corpuscles occurring in inflammation is to be looked upon as a physiological reaction of the organism directed to its preservation, and it seems probable that the salutary import of this process may also hold good for the local œdema. As the result of the injury of the capillary walls a more concentrated lymph is poured out—i.e., a lymph containing more proteids to serve for the nutrition of the cells of the part. Whether or not this is the case, the presence of this concentrated lymph must be of great use to the organism in the regeneration of tissue which follows on inflammation.

We know less clinically of the cases in which the injury to the vessel-wall is brought about by a poison circulating in the blood. I have already described to you the class of animal poisons which were grouped together by Heidenhain as his first class of lymphagogues. I showed in my first lecture that the chief action of these bodies was on the capillaries of the liver. Their action, however, is not absolutely confined to this organ. I have experimental evidence that there is a certain degree of increased permeability of the intestinal capillaries after the injection of these bodies—an increased permeability which is brought into evidence only after raising to a certain extent the pressure in these

Digitized by Google

capillaries. These bodies, however, can also affect the capillaries of the skin. In a number of the experiments in which these bodies have been injected we may observe a rapid development of an urticarial eruption on the skin, and you are all familiar with the fact that the ingestion of the animals from which these bodies are derived (mussels, crayfish, lobster) is often followed in man by an eruption of urticaria, which may or may not be accompanied by other symptoms of poisoning. The sudden onset of urticaria and similar eruptions in man, combined with the fact that their distribution may correspond with that of a certain nerve, has given rise to the supposition that these œdemas may be nervous in origin; that, in fact, we have an increased production of lymph under the direct influence of the nervous system.

If lymph were to be looked upon as a secretion we should expect from analogy with other secretions to find it subject to the central nervous system, and at the time when I was fully imbued with the new faith, the secretory hypothesis, I made diligent search for direct evidence of the influence of the nervous system on lymph-formation. The results of my experiments were, however, opposed to such a hypothesis. In every case where nerve section or excitation gave rise to increased lymph-production in any part, I found that the increase was due primarily to a rise of capillary pressure in the part and was, therefore, only a secondary effect of the interference with the nerve. The best-marked case of so-called nervous œdema is the unilateral œdema of the tongue, which may be produced by stimulating one lingual nerve. Now the stimulation of the lingual nerve causes extreme vaso-dilatation of the vessels of the tongue, and the increased lymph-production in the tongue is evidently the direct result of this vaso-dilatation and consequently increased capillary pressure. Here, as in all other cases where one wishes to produce œdema, one must not rely simply upon one factor. In the majority of cases the œdema produced by stimulating the lingual nerve—i.e., by a simple rise of capillary pressure—is but slightly marked. One can, however, produce a very fine œdema of the tongue if one aids the filtration process and diminishes the forces tending to absorption by the injection of a large amount of normal saline solution into the circulation. I believe that all cases of so-called nervous œdema can be explained by the circulation of some lymphagogue substance in the blood combined with local vaso-dilatation, which may often be hysterical or central in origin.

One of the most important forms of dropsy—i.e., that which accompanies renal disease—was placed by Cohnheim in the category of inflammatory dropsies, and this seems a necessary conclusion in view of the fact that we are unable to trace any adequate mechanical cause, such as raised capillary pressure, for the increased transudation. We know very little more about this form of dropsy than was known in Cohnheim's time. The discovery of lymphagogues naturally suggests that the change in the vascular endothelium in Bright's disease, which leads to its increased permeability, may be due to the circulation in the blood of some poisonous substance belonging to this group of bodies. This possibility is favoured by the results of one experiment in which I injected blood serum from a uræmic patient into a dog and obtained marked quickening of the lymph-flow from the thoracic duct. The conditions in Bright's disease are, however, much too complicated for us to come to any conclusions without carrying out a long series of experiments on the subject.

This cursory examination of the alterations of physiological conditions present in the various forms of dropsy brings to light one important fact—a fact on which much stress has already been laid by Cohnheim. In all cases the primary cause of œdema is an increased transudation. The normal mechanism of absorption may for some time hold this process in check, but in all cases where the increased exudation endures any length of time subsidiary events cause a breakdown of the absorbing mechanism and the occurrence of œdema. On the other hand we know of very few cases in which œdema can be ascribed primarily to a diminished absorption. Obstruction of the lymphatics can rarely occur, owing to the multitudinous anastomoses of these canals; when a complete obstruction does occur the result seems to be rather a general hypertrophy of the connective tissues (as in elephantiasis) than a true œdema. In all cases, however, where we find dropsy we may say that in addition to the primary increased exudation there is also a derangement of some part of the absorbing mechanism.

The Annual Oration

Delivered before the Medical Society of London on May 18th, 1896.

"THE BREAKING STRAIN."

BY W. H. ALLCHIN, M.D., F.R.C.P. LOND.,
HONORARY LIBRARIAN TO THE SOCIETY; SENIOR PHYSICIAN TO THE WESTMINSTER HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—Among the many and varied phenomena presented to our observation by living beings there is no one that recurs with such persistent frequency, no one that our experience leads us so inevitably to anticipate, as that such a being will in time, whether long or short, cease to exhibit those manifestations in virtue of which we speak of it as living, or, in other words, will die. It has seemed to me that I might, and I hope without too great presumption, profitably occupy the occasion which the courtesy of the council of this society has extended to me in putting before you some considerations which are connected with the investigation of this problem. A fundamental explanation of it I do not pretend to—that were impossible, as impossible, indeed, as it is to affirm the "why" of any other "of the sense impressions distinguished by our perceptive faculty." But it at least is as capable of scientific treatment as other phenomena, whether they be associated with living or non-living material. And the collection and classification of the facts connected therewith, as well as the recognition of the sequence and relative significance of these facts, are as much called for and as reasonably to be expected as in any other problem of natural science.

The immediate practical bearing and importance of so difficult and recondite a question in physiology may perhaps be far to seek, even for a body of medical men actively engaged in the practice of their profession and eager to avail themselves of any new weapon that science may furnish them with in their contest with disease. But I think now and then a short time may be advantageously spent in the consideration of subjects which, though not of immediate practical use, do seem to furnish some principles of general application, and to suggest some lines of coherence among the many scattered and apparently isolated observations which we are so constantly recording. It is pleasant occasionally to dissipate in generalities, to see what bearing phenomena may have to one another, and indulge therein by way of relaxation from the laborious accumulation of individual facts. The Medical Society, no less than other societies which claim to be scientific, regards, and properly regards, with some hesitancy of approval the time devoted to theory and speculation. But we have to-night reached the end of an active session, and the knowledge of this as well as the recollection that my present contribution is not followed by discussion has led me to take, not, I hope, an undue advantage of your forbearance by offering some remarks upon a subject which, I fear, may have been already dubbed by some of you impractical and transcendental.

It will be well to obtain at the outset as complete an objective conception of the phenomena as we can—to ascertain and realise as far as possible the facts of the case. To begin with it is clear that we mean by death a condition of matter when it has ceased to exhibit any of the properties which we call living. For a thing to be dead implies, properly speaking, that the thing has lived, and the term is inapplicable—or should be, were we precise in our language—to material that has not been just previously living. It will be impossible, therefore, to enter on the consideration of death without some preliminary agreement in notion of what is meant by life, which, after all, is only another aspect of the same problem.

Conformably to the principles of modern science we seek—*pace* the new vitalism—to refer the investigation of "vital phenomena to their physical and chemical counterparts or analogies"[1]—to refuse, in fact, to consider vital problems as

[1] Ludwig and Modern Physiology, by Professor Burdon Sanderson, F.R.S. Science Progress, March, 1896.

understood that cannot be measured by the standards and methods employed in the investigation of physical and chemical manifestations, fully conscious that our results merely end in description and not in explanation, and result only in ranging our "perceptual experience" within the scope of postulated natural laws, and not pretending to assert a supersensuous causation. It is also obvious that to form any idea of life and its correlative death it will not suffice to confine one's attention to the higher animals and plants, still less to man only, but that to obtain a thoroughly comprehensive notion the investigation of the simplest forms of both kingdoms must be included, and so, by excluding the highly specialised functional manifestations exhibited in the most developed, ascertain what is common to all from the simplest to the most complex, thereby reducing the phenomena to their simplest terms. So regarded, we find that the essential facts of vitality as ascertained by observation, experiment, and experience are: 1. The invariable presence of a certain material of very easily recognised physical properties, but of a highly complex but as yet undetermined chemical composition and molecular structure, known as protoplasm, which recent investigation has tended to show is not so homogeneous as was originally thought, though the details of its arrangement the microscope as yet has imperfectly revealed. 2. Such material occurs in isolated and distinct particles of exceeding minuteness, probably always, even in its simplest form, differentiated into cytoplasm and nucleus—the cell; or as aggregations of such particles, frequently in association with other materials less complex in composition and not possessing the properties we call life. 3. Given this substance, we call it living when it exhibits certain special forms of energy to which the collective term "irritability" may be applied, or more specifically "contractility," "nerve power" and "secretion." They are accompanied invariably by the liberation of heat and probably always, certainly often, by electrical manifestations, both of which are identical in nature and measurable by the same means as the heat of our fires or the electricity produced by our batteries. I am not concerned now to discuss how far these living energies are mutually convertible, or whether they are or are not correlated to the associated heat and electricity; it is sufficient to say that matter which presents these characters is called living, and unless they be present life is absent. Further, it would seem that for their manifestation there must be some immediate antecedent existing agent, some stimulus, whether that be of a gross and obvious character brought to bear from outside or more subtle and obscure arising intrinsically. For the display of these properties and essentially included in the conception of life is the presence in the cell of an adequate supply of non-living material—food, whereby its nutrition, as we say, is maintained. Regarded more closely, the three-fold functions above enumerated are the outcome of, or the expression of, protoplasmic nutrition, and as they are the essentials of vitality, nutrition and life may be to that extent regarded as synonymous terms. So far what I have said is within the range of verification by observation. The simplest speck of living matter, call we it animal or plant (or multiply the difficulty by speaking of an intermediate group, the Protista), equally with the highest known organism, may be seen to move, not infrequently in a manner strongly suggestive of purpose, to avoid or pursue in its movements this or that object, to engulph other material upon which it feeds and upon the presence of which its continued existence as living matter is absolutely dependent. Equally is it known by observation and experiment no less than by experience that the manifestation of life is subject to certain conditions of the environment of the cell, conditions that are familiarly known as temperature, moisture, sunlight, and atmosphere, including a due supply of oxygen and the like, certain degrees of which are favourable, as others are fatal, to the vitality of the protoplasm. Experience provides us with no knowledge of vitality apart from these conditions, and the vital phenomena we are familiar with may be regarded as the resultant of these external influences brought to bear upon the nutritive changes taking place in protoplasm. But just as for purposes of clearness of thought and to obtain the desired objective conception of our subject we consider the intrinsic proteplasmic changes apart from the influence of the extrinsic environment, so we have further to recognise that the range of variation within which the latter is consistent with life is very considerable and that the living protoplasm has a considerable range of adaptability by which it adjusts itself to altered conditions. This power of adaptation we are in the habit of regarding as an inherent property of living matter, a factor of its vitality, just as the power of self-nutrition and the manifestation of irritability are other factors, all inextricably involved and perhaps but different aspects of one and the same. If to these qualities be added the tendency to death which sooner or later asserts itself we have a summary of the characters by which we affirm that a given object lives.

It is necessary to consider a little more in detail what was just now spoken of as nutrition to ascertain, as far as may be, the intricate nature of the processes therein included as bearing on their relation to the particular subject of my present remarks. That the living being is dependent on food, that this food undergoes certain changes in the living tissue, and that certain waste products of such changes are thrown off, are among the commonplaces of our experience and are questioned by none any more than the fact that, associated with this continuous ingestion, change, and excretion, there are evolved certain energies, some of which are peculiar to living substance. Indeed, so precise is most of our knowledge on this point that what has been called the balance-sheet of energy, in which the work done by the body (in this case the body of some one of the higher animals) is accounted for by the food-stuffs used, has been prepared with such an approach to accuracy as to justify the expectation that it will ultimately be capable of being presented in such a form as to satisfy the most critical physiological auditor. But beyond such a view—a very superficial view—of the question there remain deeper aspects of the problem where we are not nearly on such firm ground and where hypothesis and conjecture do duty at present for more positive knowledge; but so long as these hypotheses are admitted as such and are in harmony with, or at all events not flagrantly opposed to, other fundamental concepts, we may claim to be pursuing the right path, at all events for the present, and until we are brought to a stop by the proof or even strong probability that our assumptions are erroneous. It is in respect to the exact relationship which exists between the ingesta and the living elements of the tissues in the course of those changes which eventuate in the liberation of vital energy that conjecture prevails, and, as may be supposed, no single hypothesis is wholly accepted. Are we to consider that the living protoplasm, whatever may be its ultimate structure, behaves as regards the pabulum supplied to it as does a piece of machinery, say a steam engine, where the water and fuel are so disposed as to furnish steam power, with the result of a slight wear and tear of the mechanism and a discharge of waste in ashes and smoke, and that the machine is merely a suitable arrangement for effecting the required changes in the material consumed, itself undergoing no—or practically little—alteration in the process? The relationship of the living structure (mechanism) to its fuel seems scarcely so simple as this; some at least of the food-stuffs duly elaborated in the processes of digestion, in the lymph and blood channels, and, possibly, also in the liver through which they pass before reaching the tissue elements, would seem to be incorporated in the very tissue itself, to form an integral part of it, to be raised up to that height of molecular complexity and corresponding instability which pertains to the living particle, which is no sooner reached than it over-topples, so to speak, to be as continuously replaced, falling from the zenith of complexity to some more stable construction, disengaging energy in the change, and so passing from the pinnacle at which it may be pronounced living, which is no sooner reached than it breaks down into the condition again of non-living matter from which it had just been built up. In such a fashion it may be conceived that this living material is maintained, that the progressive stages of construction (anabolism or assimilation) passing over at a certain point, as yet not grasped, into a rearrangement of molecules of the destructive or catabolic order, constituting thereby a perpetual succession of interchanges, a "cyclosis in which the organism returns after every cycle to the same point of departure, ever changing yet ever the same"[2]—in fact, life itself.

It would seem that but a small proportion of the nutritive ingesta is destined to actual living tissue construction, and

[2] Address in the Section of Biology at the meeting of the British Association for the Advancement of Science, 1859, by Professor J. Burdon Sanderson, M.D., F.R.S.

Digitized by Google

that proportionately only a little of the total resulting vital energy is associated with the interchanges here postulated; but no hypothesis, as far as I am aware, has yet ventured to suggest exactly which of the specific energies are thus liberated, or, indeed, how far, if at all, they are independent of the probably less complex interchanges which take place in that major portion of the ingesta which are regarded as never becoming actual constituents of tissue, but which consist mainly of an oxidation process carried out within the range of influence of the protoplasmic metabolism. The terms "fixed" and "circulating"—the former singularly inapt—have been used to denominate these two varieties of food as it finally reaches the tissues. Such, then, in summary, is what we mean by life, the processes of which are the subject matter of the physiologist's inquiry, to become the province of the pathologist when they overstep the ill-defined line which separates health from disease. By experiment and observation, constantly aided by the progressive advance of chemistry and physics, is our knowledge becoming more accurate and precise. But at the beginning and end of the subject, so to speak, are questions to which as yet but the most uncertain answer can be offered. Given the living protoplasm, given this material with its vitality, how has it come into being, how does it come to an end? With the "why" as an explanation true science has no concern, but the "how" is its legitimate scope of inquiry. Different as these questions may be at first sight they are not, I venture to think, as different as they may appear to be, and I suspect any knowledge of the one will materially assist to a comprehension of the other.

Before proceeding to consider the nature of death, what is implied by it, and how it comes about, it is worth while to inquire whether death is an invariable termination to life, whether, in short, every being that lives does sooner or later die. If we confine ourselves to the higher forms of life the reply would undoubtedly be "Yes," but this cannot be so readily affirmed if we regard the simplest forms of existence. Here we note a close connexion between the mode of origin of life and the conditions of its termination. Universal experience shows that such beings as propagate sexually, whether animals or plants—or, in other words, beings which originate from the union of distinct sexual elements and themselves consist of aggregations of cells and cell derivatives resulting from this union—will sooner or later die, even though, so far as can be recognised, their surroundings and conditions of existence remain the same as when their vitality was at its prime. On the other hand, those organisms which reproduce by a process of fission cannot, with a possible partial exception to be presently noted, be said to die, but to continue their existence in their progeny, which primarily consists of the constituent material of their parents, the whole of the parent body being used up in the formation of the descendants. If we regard, as I think we are entitled to do, fissuring of a protoplasmic unit (cell) as the exhibition of an extreme and peculiar form of the power of contractility, which is possessed in some degree by all matter that is living (induced by some stimulus the nature of which is quite unknown), but only manifested on certain occasions, then we bring the reproductive act of these asexual organisms into line with the common properties of living matter and facilitate its consideration and description. If each resulting portion of a fissured cell continues to exhibit after its separate existence the characteristics of all living material as possessed by its parent, its power of self-nutrition with all therein implied, and its powers of adaptability within limits to varying conditions, and in due time to subdivide into two portions, each again continuing the *rôle*, then, indeed, such beings cannot be said to die except by accident and are essentially immortal. No greater difference in identity exists between parent cell and progeny than exists in the parent cell itself at successive periods of its own existence, consisting as that existence does of ceaseless changing with continuity of character. All unicellular organisms, however, do not appear to be capable of unlimited propagation by fission. It has been long known that the infusoria, which are among the highest developed of the protozoa, do after a series of such multiplications gradually exhibit a slackness in their fissuring until at length the act is no longer repeated and the individual dies. But should the infusorian meet with another of its kind in a like state of enfeeblement, and a temporary conjugation between the two occur, they will then separate, reinvigorated with a new lease of vitality, and continue their propagation by fission until again exhausted. Such a condition is one of less complete immortality than obtains in other protozoa and protophyta, but it falls considerably short of the inherent mortality that pertains to all forms of multicellular life. Among the metazoa and metaphyta by no means can senescence and death be averted, however favourable may be the conditions for their continued existence. But even then some multicellular organisms do not wholly die. The body of the individual undoubtedly perishes, but the sexual elements contained therein, and for the production and care of which the individual soma finds its chief *raison d'être*, whereby the species may be maintained, continue to live, given only suitable conditions, and the fertilised ovum resulting from these elements, consisting as it does of integral parts of the parents, develops and grows, thus maintaining generation to generation in structural continuity. Death, therefore, which is a condition only known in the higher divisions of living beings, comes to mean a cessation of some only of the activities possessed by these beings—the greater proportion of their activities it must be admitted, and those which concern the maintenance and well-being of the individual as opposed to those by which the race is continued. It is the mass of the body that dies, that which lives or can live, conditions being favourable, constituting but a minute fragment compared thereto, in the highest forms of all a mere particle, and this participates in its partner's death unless removed to suitable surroundings. I need scarcely say that I make no reference to organisms being killed, that is to say, being subjected to unfavourable conditions of the environment. Countless myriads of immortal protozoa die, but that is due to the nature of their surroundings, they do not contain within themselves the inevitable destiny of death which they cannot avoid. Similarly myriads of the equally immortal sperm and germ elements of the higher and highest developed forms perish from like causes. My remarks obviously apply to death as a natural phenomenon, and as such it has a somewhat more restricted scope than at first appears.

The relationship of the sexual element to the enveloping and protecting soma is worth a moment's thought. Possessing as it does when suitably blended a potentiality of growth and development to the parent form, and dependent on the soma for such nourishment as it may require, it nevertheless maintains a passive existence in the midst of its surroundings, waiting, so to speak, its chances, which accident may prevent from ever coming to it. Meanwhile, the body continues to exhibit the functional activities of its vitality, however simple, however complex, until these processes of themselves gradually fail and finally cease. We are accustomed to recognise in the course of existence of a living being three stages: one of growth and development, one of maintained maturity, and a third of decline and senility terminating in death. For the most part, if not absolutely, these stages are characterised by very considerable differences both in respect to the origin of life and to the cessation of it. During the first period the multiplication of the tissue elements and their individual increase in size, and more remarkably their differentiation of structure and specialisation of function, are all at the maximum, fresh living tissue elements are formed by the division of pre-existing ones, and the generation and development of material prevail everywhere, notably, however, in one situation in a laggard fashion and sometimes scarcely at all—viz., among the portions which will ultimately give rise to the reproductive elements. Their inactivity is in marked contrast to the often rapid development of surrounding structures, they multiply but little, and differentiate scarcely at all, retaining throughout this period an embryonic character, such as they have possessed since they underwent the first stages that followed their separation from their parents. At this stage, when all efforts are put forth on behalf of the individual, its reproductive power is but slight or entirely wanting, and in the natural sequence of events, and accidents apart, death is unknown. When, however, full development is attained and the individual is complete then a difference in the relative properties of these phases is seen. The efforts of the soma are directed to the maintenance of its structural integrity. The fully differentiated tissues exhibit their own functions and harmoniously work to the same end—viz., the life of the individual. Now the reproductive elements are mature, and the individual is capable of taking part in reproducing its kind. In a vast number of living beings the sexual elements are produced in the same individual, when self-fertilisation may or may not occur; in the highest forms they are borne in different

Digitized by Google

bodies; but, be that as it may, the stage of maturity is that in which the sexual power of the individual is at its maximum, the formative functions of the tissue have largely diminished or even ceased, and death again except from mischance does not occur. Finally, after this stage has lasted a certain time more or less peculiar to each species, and not, perhaps, wholly unconnected as regards duration with the length of the preceding period, the organism begins to fail in its activities, to live less perfectly, and, as we say, to grow old, the tissue elements are no longer or but imperfectly renewed, those that remain atrophy and degenerate, the power of reproduction has departed, the individual has fulfilled its destiny, it has lived and reproduced, it now remains but to die. But death now is not an accident, it is an inevitable, inexorable event. Such a course is altogether in harmony with the principles which we recognise as natural selection and the survival of the fittest. The being that has filled its mission only cumbers the ground, consumes nourishment required for those still in the fulness of their powers, and occupies valuable space; death for such is the fittest that can happen.

In this sketch of the successive periods of existence, and for the moment confining our attention to human existence, there may be noted with advantage the relation they bear to the incidence of disease. Disease, which is but a departure from normal living, such departure being detrimental or even fatal to the well-being of the individual, associated with some changes from the normal structure, ill defined in its limits because normal structure and function are ill defined and not accurately known, induced by some unsuitability in the conditions of the environment or imperfection in the original germ plasm whence the individual developed—disease, I say, has, like death, no natural connexion with the stages of growth and maturity. All maladies occurring at this time are non-natural and are, or should be, preventable, and, apart from hereditary or congenital affections, the causes of which should have been averted in the parents or should have been prevented from perpetuation, are wholly due to external influences. On the other hand, during the decline of life disease as signifying a functional shortcoming from the normal standard of the prime is a natural incident. We may be able to show that a healthy old age is free from many of the ills commonly ascribed to it and even that some not inconsiderable reparative power may be retained by the tissues; but nevertheless it is in the natural course of things for the tissues generally, some more than others, to degenerate, to become, that is to say, less complex in chemical composition and therefore more fixed and less capable functionally. One may be surprised now and then with exceptional cases in which the nervous or even the muscular energies have been unusually prolonged, just as the procreative power is occasionally sustained until an advanced age, but however long beyond the usual they may survive there is a limit to their manifestations. Did time allow it would be interesting to compare the clinical features of the diseases as they occur at these age periods, but I content myself with pointing out the normal incidence of disease, which in all cases approximates towards dissolution, as occurring simultaneously with the natural tendency to death.

If now we pass from the soma as a whole to consider the various constituent tissues as they exist in the highest forms of life we are struck by several notable circumstances. Among the varied component parts of the mature soma, all derived from the fertilised ovum and in their earliest beginnings identical in appearance, the widest range of ultimate differentiation is attained. Whilst some, such as nerve cells and muscle fibres, represent the maximum of departure from the primary embryonic elements and with that the highest specialisation of function, others, like the white blood corpuscles and the simpler cell elements of the connective tissues or of the deeper layers of some epithelial surfaces, are but slightly removed in appearance from their embryonic ancestors, have differentiated but little, and are possessed of a far inferior range of vital capability. But a further and striking contrast exists between these two groups—viz., in respect to their ability to reproduce their kind. A fully developed nerve cell or muscle fibre is not known to divide and multiply either in health or under the conditions of disease, but when once its full structure is attained by a process of continued fission and progressive differentiation the tissue element undergoes only such changes as are involved in its nutritive activity until overtaken by disease and death. Not so the simpler forms; they are constantly multiplying, much indeed as free unicellular organisms, and for the most part their successive progenies resemble almost or quite exactly the parents. With this one cannot but remember that the simpler tissue elements here mentioned appear to be equally and perhaps mutually active in effecting those reparative changes which are necessitated by accident or disease, reverting in so doing nearer and nearer to the embryonic form, and so giving rise to the healing tissue. Here, then, from this point of view, it will be seen that the highly differentiated tissue elements, like the more complex individual, invariably die, whilst the simpler forms, in proportion as they approximate to the germinal elements and as such to unicellular organisms, retain the power of multiplication and so escape from death the longest, though they have not the potentiality of developing into an entire individual such as is possessed by the germ.

From the foregoing considerations we are now in the position to make these general statements:—1. That death as an incident in the evolutionary cycle is not inevitable to all living beings. 2. That whilst unicellular organisms are immortal those of any higher grade of structure of inherent necessity die. 3. That these latter are, given favourable conditions, continuously propagated by specialised portions of their own substance, the individual itself, apart from these portions, perishing. 4. That the power of self-division and hence of perpetuation with avoidance of death is lost by cells which have advanced beyond the most rudimentary stage of differentiation, such power being restricted to those elements which retain their embryonic character and most completely by those which form the sexual elements.

From such conclusions, then, naturally follows the question which is at the root of the subject, How is it that the vital processes decline and cease after a manifestation over a tolerably definite period more or less peculiar to each species of animal and plant, peculiar to them in the same sense as a specific size or shape is peculiar? What is the immediate antecedent to the cessation of vital activity as invariably seen in sexually propagating organisms? Whence comes, and what is the nature of, the breaking strain which disrupts the ceaseless interchanges which constitute life? It may be at once admitted that no satisfactory answer can be given, and any attempt thereat, however reasonable, only pushes the question a step further back; but even that, if sure and certain, is a gain—it would be one more stage in the ascertainment of the sequence of phenomena which is the function of science, though leaving the "first cause" still unknown as being beyond the range of our perceptive faculty. To begin with, it has been shown that all protoplasm, all living matter, is not of necessity mortal. It is only certain specialised forms of protoplasm that are so distinguished, only certain individual living beings which inevitably die. If these two groups of individuals be contrasted some clearer definition of the problem may be forthcoming. In the one case the individuals consist of but single isolated and independent particles of living matter (cytoplasm and nucleus), each possessing and manifesting all the phenomena which make up life; each particle is irritable, responsive to a stimulus and exhibiting contractility (usually so disposed as to effect its locomotion) and some solvent (secretory) action on the foreign matter which constitutes its necessary food and in virtue of which its nutrition is maintained. Each particle is endowed with a certain degree of the power of adaptation to its surroundings, which in turn exerts a modifying influence upon it; and, lastly, it can and does possess the capability of self-division, splitting its entire self into two similar parts which differ from the parent individual only in bulk—a difference that is rapidly lost by simple growth from suitable ingesta.[3] Such individual beings, then, are all capable, all living, each one is complete in its vitality, and never except by accident dies.

The individual of the other group consists not of one but of many cells aggregated into colonies and masses of countless sizes and shapes; such cells, incapable for the most part of independent existence and mutually dependent for their well-being, collectively constitute the living individual. The organism thus constructed, so far as living goes, does no more than the simpler unicellular being, but it lives more perfectly, more elaborately, its vital processes of movement, of nervous manifestation, of secretion—in short, of its entire nutrition—are developed and exhibited at a higher pitch of perfection; its range of adaptability to

[3] It cannot reasonably be argued that this division into two is a virtual death of the parent individual in anything like the same sense that we speak of the death of a higher animal or plant, or that the progeny of the latter perpetuate their parents in the same sense that the resulting halves of a fissured cell do so.

Digitized by Google

the environment, of resistance or yielding to surrounding influences, may be greater, but in the long run it attains no further object than that accomplished by its simpler neighbour—viz., the propagation of its species, whilst the price it pays for its greater elaborateness of living is its inevitable death. Thus stated it would seem that the differences between these groups are of degree rather than of kind. The more complex vitality of the one is associated with a greater complexity and differentiation of structure, a subdivision of labour, that is, special functions being associated for their more perfect performance with more highly specialised structures, though these same structures, in proportion as they are differentiated, lose the power of self-division which is possessed in common with the other vital powers by the simplest form of protoplasm. These are but grades, and all intervening degrees are to be found between the highest and lowest beings. Nor is the difference as regards the incidence of death fundamental; whilst the one individual lives wholly in his immediate descendants, the other lives but in part, his own identity being lost in his death. But however much this mode of stating the case may conduce to a clearer understanding of the problem at issue, there still remains the unsatisfied question, How is it (or in common phrase, what is the cause of?) the organism, once that it has reached its maturity, in the full plenitude of its powers both for its own existence and for its own perpetuation, gradually comes to fail, grow old, and die? Why should it not, when once fully established, so continue for all time and remain immortal itself as well as perpetuated in its descendants? Wherein is the explanation to be sought? Is it in the continued effect of surrounding circumstances and conditions the adverse influence of which gradually prevails, or is it from some inherent defect in the vital processes which becomes intensified by time and constant repetition? In whatever direction the source and nature of the disturbing influence are to be looked for, it would assuredly seem to be in that same region where are to be found the conditions which determine the chemical and molecular changes that constitute nutrition and vitality itself; and inasmuch as cell division, which is the essential of propagation, is but a phase of that aspect of nutrition known as contractility, it would appear that what knowledge we may come to acquire of the intimate nature of life will equally provide us with the explanation of the conditions of its origin and of its termination, inextricably linked as these phenomena are. Conceiving as we do that the energies of vitality are the sensible expression of continuous interchange in a highly complicated material, one phase of which is a building up, or assimilation, to be succeeded at some higher degree of complexity and instability by a breaking down and disassimilation, is it in the anabolic stages that the inherent antecedent that finally arrests the metabolism, and with it life, is to be found? or is it that in the catabolic descent materials may be formed which exert a slowly increasing pernicious influence on the entire process, autogenetic poisons, in fact, that are invariable accompaniments of protoplasmic change? Or, lastly, may it be some failure in the stimulus, the existence of which is involved in our conception of this same protoplasmic activity? Conformably with our fundamental hypothesis of the nature of nutrition it is difficult to see any other direction in which to look for our desired antecedent. Expressed in terms more in accordance with our grosser conceptions of physiology, does death result from some imperfection in the nutritive material (ingesta) or in some toxic product of waste (egesta), or for want of the needful stimulus to the very changes which involve the material and determine the products? That it is the soma that dies and that the life of the soma or individual is identical with its nutrition would, consistently with our present hypothesis, make it probable that somewhere within these concepts what we are seeking is to be found.

As may be supposed, many suggestions have been offered which find their place in one or other of these categories. Some, with Mr. Herbert Spencer, have sought to explain the phenomena by assuming a failure in the nutritive supply or in the ability to appropriate the ingesta on the part of the organism, the same conditions, in fact, as those which determine the limits of size peculiar to each living being. However true this may be, it gives no explanation for the inability displayed by the tissues. Among the theories which are based upon the determining cause of death being produced in the course of the changes which constitute life may be mentioned that of Lendl. According to him the protoplasm in the course of its living forms waste products from which the germ plasm at first starting is free; as the cell divides these materials—termed by him "ballast"—are restricted to one of the resulting pair, and in the course of the subsequent growth and development of the organism those morphological units which form the perishable soma are loaded with ballast, whilst those which are destined to the perpetuation of the species, whether they be limited to the sexual elements, as is usually the case, or form a part of the general structure, as seen in some leaves—e.g., begonia—are free from the noxious material and in consequence escape death. It need scarcely be said that no proof of this hypothesis exists any more than there does of the suggestion that it is the presence of an aldehyde in living protoplasms which serves as the stimulus to its activities and that death is caused by a want of this substance. Others have assumed that the stimulus to vitality emanates from the nucleus which in the process of living becomes gradually exhausted and is finally extinguished.[4] There is one circumstance which seems to bear a very constant relation to the onset of death—viz., the reproductive effort. In very many beings this effort is made but once, and then as a rule death soon follows. In others the effort is capable of being repeated over a period (maturity) of varying length, but when it fails senescence sets in. A review of all the circumstances would seem to show that failing vitality follows the cessation of reproductive capability rather than that this latter fails because of approaching death, and, if we may speculate with others, it appears to be among the possibilities that the lacking stimulus is to be found in connexion with the sexual elements themselves—some ferment, may be, such as we assume to exist in those lately recognised internal secretions the potency and influence of which in respect to nutritive processes we are but just gaining a glimpse of. An analogue for my suggestion is perhaps to be found in the case of the thyroid and thymus glands which exercise a profound control over tissue nutrition and even over growth itself. So may it be with the reproductive organs and their products. Exhausted by their efforts to perpetuate the individual, they no longer liberate that stimulus (call it provisionally ferment, internal secretion, or what you will till more precise knowledge defines it) which is needful for the maintenance of the nutritive processes of maturity, and for lack of which the individual deteriorates and dies. May it be that there is a real truth embodied in the experiments of Brown-Séquard, however incomplete they have hitherto been in results?

Based on some such considerations as these I have put forward must be, I take it, the full comprehension of the nature of death as we are in the habit of witnessing it at the bedside. We speak of cardiac failure, of fatal intoxication, whether from within or without, of arrested nerve influence and the like, but the real meaning of such phrases, imperfect as they are and often quite inadequate to explain why death should have happened, must be somewhere in the region I have now been groping in. Moreover, the very foundations of prognosis, if not of treatment, so far as this may attempt to modify nutritive processes by drugs or other reagents, must be built upon an understanding of the intimate nature of life and the inherent causes of its failure and cessation.

A NOTE ON SURGEON-LIEUTENANT-COLONEL LAWRIE'S ADDRESS ON THE CAUSE OF MALARIA.

BY GEORGE THIN, M.D. ST. AND.

IF, as I believe, the man who stimulates interest in a new subject is a public benefactor, Surgeon-Lieutenant-Colonel Lawrie deserves the title. Amongst the many in whom such interest is excited there is almost the certainty that some few individuals will be induced to apply themselves to its study, and there is thus a great likelihood of fresh knowledge being obtained. The celebrated telegrams to the *Times* intimated to the whole world that Surgeon-Lieutenant-Colonel Lawrie was engaged in the study of malaria, and thousands of readers for the first time learnt from these telegrams that the Italian physicians believed that malaria

[4] For the discussion of various theories on the intimate nature of death see La Structure du Protoplasme et les Théories sur l'Hérédité par Professor Delage, 1895.

Digitized by Google

was caused by a parasite, and by reading them many medical men doubtless learnt for the first time that there might legitimately be two sides to this question. If I judge by my own experience, Surgeon-Lieutenant-Colonel Lawrie's lecture at Bombay, reported in the *Times of India*, the *Indian Lancet*, the *British Medical Journal*, and in THE LANCET of May 16th, has fully sustained this interest. As an evidence of this, I may remark that I have received three copies of the *Times of India* from different sources and one of the *Indian Lancet*, and some urgent requests for information as to what it all means. I am not sure that even this would have induced me to solicit the courtesy of the pages of THE LANCET were it not that, although my name is not mentioned in Surgeon-Lieutenant-Colonel Lawrie's lecture, some pungent remarks are made in it which have direct reference to a publication for which I am responsible; and I do not consider that I should be doing either myself or Surgeon-Lieutenant-Colonel Lawrie justice if I were to pass over his criticisms without remark. The reading of a paper on the Parasite of Malaria by Dr. Marshall of Rio Tinto and myself at a meeting of the Royal Medical and Chirurgical Society was used by the Council as an introduction to a discussion on the whole subject, and I undertook the duty of prefacing the reading of the paper by a short exposition of the views at present held regarding the relation of the parasite to the various forms of malarial fever. To render my remarks more intelligible I used diagrams, copied from the works of the authors whose views I endeavoured to explain, and in order that the readers of THE LANCET and *British Medical Journal* might more easily grasp the meaning of the brief reports of my introductory speech, reduced engravings of the diagrams were printed at the head of the report. Surgeon-Lieutenant-Colonel Lawrie remarks of these engravings that Laveran's bodies (the term by which he designates what we call the parasite) "are not such cells as are depicted in the pictures of THE LANCET and *British Medical Journal* of Feb. 15th, 1896. These are not correct representations of Laveran's bodies. Some of them appear to be drawn from the imagination, others, especially the rosette form, are caricatures of vacuoles and crenating or disintegrating blood-cells." Now, will the readers of THE LANCET imagine for a moment what this criticism implies? It signifies either that the person employed to make the drawings for the diagrams misrepresented the bodies he was employed to copy or that Marchiafava and Bignami are not familiar with vacuoles and crenating or disintegrating blood-cells. As a diagram is only intended to represent the leading features of a drawing, mine may not have been exact copies in every detail of the original drawings, but the references to Marchiafava and Bignami's works will show that they are correct in every important particular. If this is conceded, Surgeon-Lieutenant-Colonel Lawrie's statement can only be justified by assuming that Marchiafava, a Professor of Pathology of long and great experience, who has been studying blood for considerably more than a decade, and Bignami, the chief assistant in the Pathological Laboratory of the University of Rome, who has also been engaged for several years in the study of blood, does not know a vacuole in a red blood-cell when he sees it, and cannot recognise a crenating or disintegrating blood-cell. The mere expression of the supposition shows its absurdity. Such mistakes are possible by imperfectly instructed beginnners. Nay, I have even seen them made in illustrations of a paper on malaria (not published in Europe), but errors of this kind could not be put on record in Italy where learned societies know something of the value of the observations for whose publication they are responsible. What I have said ought to be enough to show what weight should be attached to Surgeon-Lieutenant-Colonel Lawrie's criticism, but if it is likely to serve any useful purpose I may be pardoned for observing that all the appearances in the challenged pictures, except the appearances of a sporulating crescent from Grassi and Feletti's work, have been verified by myself, and if any student of the subject who is interested will procure a copy of Dr. Marshall's and my paper he will find it illustrated by a plate which shows not only these phases but many intermediate ones. The drawings answer in the affirmative Surgeon-Lieutenant-Colonel Lawrie's question as to whether the successive stages of the development of each species of parasite shown in the reduced diagrams belong to the same body in different phases of its existence. This paper has just been published in the Transactions of the Royal Medical and Chirurgical Society, the papers in which are now to be had separately at a nominal price, and in this one, which I believe costs a shilling, will be found a coloured plate showing the different developmental stages of four varieties of the parasites of malaria. The successive phases were drawn from nature, their continuous development in a selected patient being in each case chosen for illustration. For Dr. Marshall and myself I absolutely disclaim the imputation of not being able to distinguish vacuoles and crenating or disintegrating blood-cells.

Human nature being what it is, it is impossible for any investigation to engage the attention of various observers without a certain amount of the personal element making itself manifest. Nor is this altogether to be regretted. Rivalry within certain limits whets the desire and capacity to work, and science is the gainer; but these limits are very easily passed, and I am not sure that we are not passing them now in this malaria discussion. I would hardly refer to this element in Surgeon-Lieutenant-Colonel Lawrie's paper if it did not recall a remark that is printed in the report of the discussion in London. As a corresponding impression appears to have been made simultaneously in Bombay, I may explain now that in omitting the names of English and American authors it was not from any disposition on the part of Dr. Marshall and myself to overlook the claims of Anglo-Saxon workers as compared with an undue tendency to overestimate the claims to consideration of the Italian physicians and naturalists whose views we had been quoting. Surgeon-Lieutenant-Colonel Lawrie's remark about the "devoted worshipper of parasites and foreigners," although it is not addressed to us, was probably suggested by our frequent reference to Italian names. I think these expressions are suggested by a mistaken idea. Already the modern literature of malaria has become so extensive that only the authors of bibliographies can be expected to enumerate all the men who have been industriously working at the subject. Those workers who may prove successful in adding a solid contribution to our knowledge will get the credit of their work irrespectively of authors and of nationalities. In quoting an author in my introductory speech, what was in my mind was not his nationality but what he had done. Now what are the great things that have been done in connexion with the malarial parasite? When speaking of the discovery of its existence is it possible to avoid mentioning Laveran? When speaking of the discovery of the quartan and tertian parasite as separate species is it possible to be silent over the name of Golgi? When mentioning the virulence of the irregular and pernicious fevers of Southern Italy and many other parts of the world is it possible to pass over the name of Marchiafava, who has shown that the parasite which causes them exists as a distinct variety? When discussing the crescent body, that enigmatical form, how is it possible not to explain the views of Grassi and Feletti? Not even excepting Laveran, whose position is unique, these men may from an insular point of view be spoken of as foreigners, and there are people to whom their names may not seem homely; but whatever their names and whatever their nationality both their names and their nationality are linked indissolubly with the discoveries which they have made. True they are mostly Italians, but we ought to be pleased to acknowledge that after Laveran's discovery all the important work has been done in Italy. How much of our knowledge of malaria would still be wanting in precision if it were not for the experiments by which it was shown that if the blood of a man which contains one species of the parasite is injected into the veins of a healthy man that man will develop malarial fever of the type from which the first man suffers, and that in his blood there will develop the same species of parasite that is contained in the blood used for inoculation. By these experiments the existence of separate species of the parasite of malaria was definitely established, and all these experiments were done in Italy. What is there of the first importance that so far has been done in the other countries of Europe and in America? All that we have done is to verify the work of the Italians and endeavour to find methods by which the clinical observer may more readily discover the existence of the parasite and to speculate as to the directions in which future work may throw light upon the yet unsolved problems. The great question as to how the parasite of malaria gets admission into the human body is yet unsolved and offers an attractive field for investigation to workers in four continents.

The countrymen of John Hunter, Jenner, and Lister can well afford to applaud ungrudgingly the great and laborious work of the Italian physicians, and I hope we shall hear no

Digitized by Google

more of comparisons which have nothing better to justify them than the sound of a name or a nationality.

What is the proof of a certain appearance being that of a parasite? Amongst other evidences the chief point is that an organism or organic structure grows and multiplies and reproduces its kind. This can be absolutely proven in regard to what we call the malarial parasite, and what Surgeon-Lieutenant-Colonel Lawrie thinks is a degenerative blood-cell. The proof of this is already abundantly given in the Italian writings, and an excellent *résumé* with original illustrations will be found in Mannaberg's book. A similar proof will be found in the drawings illustrating the paper by Dr. Marshall and myself, and additional evidence will be found in the plate which will shortly be published illustrating my paper on the parasite of the pernicious fever of Sierra Leone in the same volume. The whole cycle of the organism, from the nucleated spore, *not developing within the red corpuscle to begin with*, but coming in contact with it, then entering it, becoming larger, and developing in it separate nucleated spores, is illustrated in these two papers, in complete confirmation of previous descriptions, if confirmation is necessary. Surgeon-Lieutenant-Colonel Lawrie only found some of the stages in the patient whom he showed at Bombay, and the sporulating stage was not seen; but this does not justify the remark that "no evidence has been adduced to support the theory that Laveran's bodies sporulate, or, if they do, that the act of sporulation is periodic." I need not again refer to the Italian writers who have all described and drawn the sporulating parasite, but content myself with stating that I demonstrated under the microscope, at the meeting of the Royal Medical and Chirurgical Society, all the phases of the parasite, from the spore stage to the sporulating stage, and Dr. Pringle, by the use of his beautiful photographs, showed us these stages on the screen with the lantern. I shall be pleased to demonstrate these or similar preparations to anyone who has the praiseworthy curiosity to wish to satisfy himself by actual examination of microscopical preparations. The intra- and extra-corpuscular cells described by Surgeon-Lieutenant-Colonel Lawrie as being found in his patients' blood are, with the crescents, all that is usually to be found in blood taken from the finger of patients affected with the forms of malaria produced by the parasite of irregular fevers discovered by Marchiafava, and of themselves I admit their nature might be well open to discussion. If Surgeon-Lieutenant-Colonel Lawrie has not seen more than he describes in this case or shows in his diagrams I can quite understand his scepticism. But if blood is taken from the spleen in these cases the sporulating stage will be found, and it is another merit of the Italian physicians to have shown this. To satisfy oneself that the malarial parasite is indeed a parasite, having an independent cycle of existence, it is necessary to examine blood from the finger in quartan or tertian ague, or blood from the spleen in the fevers caused by hæmamœba præcox, the parasite of the summer-autumn fevers of Rome. In some cases these can hardly be found even in the spleen, and I have verified by post-mortem examination that the brain may contain numbers of parasites and the spleen and peripheral circulation be almost entirely free from them. The localisation in irregular fevers of the pernicious parasite in special organs and its rarity, or even absence, in the peripheral circulation is a reason why examinations of blood taken from the finger in fevers in India and elsewhere so often show no parasites. I have satisfied myself that it is often very difficult in Indian fevers to find a parasite in the blood from the finger, although the pigment-laden white corpuscles often show clearly the nature of the case, and are a proof that the parasite is propagating itself in the blood in some internal organ.

The first studies of the malarial parasite should be made on quartan and tertian fevers, in which all the phases can be found in the finger blood. In the irregular fevers common in India the knowledge that can be acquired from the blood from the finger is often very incomplete.

Fortunately for my present purpose it is unnecessary to follow Surgeon-Lieutenant-Colonel Lawrie in his statements regarding the formation of the formed elements of the blood. The fact that he observes a swarming movement in the white corpuscles of the frog similar to the swarming movement of pigment granules of the malarial parasite proves nothing either for or against his views. It shows the liability of very minute inert bodies to oscillate in a fluid medium. There are two kinds of movement of the minute pigment granules to be observed in the parasite. There is the active oscillation which is due to physical causes, and which is similar to a movement of minute granules often seen in leucocytes, quite different from any protoplasmic movement associated with life. There is another kind of movement of pigment in the living malarial parasite in which the granules follow each other in fixed directions, evidently indicating streams in the protoplasm, and of a totally different character from the oscillatory movement with which we are all familar, and which, I may safely say, has never been observed by Surgeon-Lieutenant-Colonel Lawrie in the white corpuscles of the frog.

Histologists are all familiar with the clear spaces seen in the fine meshwork of the protoplasm of a white corpuscle when it is examined by a high power, which Surgeon-Lieutenant-Colonel Lawrie appears to consider to be cellular in their nature. They are found in the protoplasma of amœbæ, and that they are not young cells can be shown by the fact that they contain no nuclear elements. In stained preparations it would be impossible to confound them with a sporulating parasite, in which, when the staining is properly done, each spore is seen to contain a well-marked nuclear body. (For the technique best adapted for this demonstration I refer to my paper in THE LANCET of July 6th, 1895.)

I am far from wishing to prejudice the value of Surgeon-Lieutenant-Colonel Lawrie's investigations into the development of the blood, but it cannot be estimated correctly until he gives us a more detailed description of the objects he describes than is to be found in his address, and until they are fully illustrated by coloured representations drawn to scale. As this is a field of study in which much remains to be done it is to be hoped that Surgeon-Lieutenant-Colonel Lawrie will continue the studies that he has begun with so much zeal and energy, and eventually present the results which he obtains in a form in which they can be appreciated by physiologists. His views on this subject, however, whether they are right or wrong, have no real bearing on the question of the existence of the parasite of malaria. The most characteristic form in which we see this parasite—the sporulating body—has apparently not been seen by him, and of course we cannot expect him to trace for us its development from a white corpuscle. Even the forms which he has seen he has not traced in any form of development from a white corpuscle, and only infers their genetic relation from the trifling and unimportant fact that both bodies contain minute granules in active movement. The repeated demonstrations of the development by multiplication inside the red blood cells of the young amœbæ to the formation of from eight to twenty spores, according to the species of parasite, is only got over by an unhappy attempt to throw doubt on the power to observe and to describe of a great number of highly-trained histologists and pathologists. The existence of the parasite of malaria rests on the same kind of evidence and on as good evidence as the belief that cancer is caused by an abnormal epithelial growth. The latter doctrine must have been accepted at one time by thousands of medical men, who, although they never saw a section of cancerous tissue, wisely gave their confidence to observers whom they knew to be competent. Surgeon-Lieutenant-Colonel Lawrie in his address has given no reason why a similar amount of confidence should not be given to the competency and honesty of the scores of highly-trained men in Europe and America who have described the complete development or cycle of the parasite of malaria.

It is with pleasure that I refer to Surgeon-Lieutenant-Colonel Lawrie's valuable experimental work when he injected malarial blood into dogs and monkeys. He found that this did not lead to a multiplication of Laveran's bodies, which is valuable confirmation of previous work done in the same direction.

Before closing these remarks I should like to be permitted to say something regarding what may be expected from India in relation to these studies. I do not see that we had any reason to expect much more to have been done than has been done already. Doubtless there are many medical men in India and much malaria, but there are many medical men in England and much phthisis, yet how few of them have contributed anything important to our knowledge of tuberculosis and the tubercle bacillus. I have worked at both these subjects, and it may be of some use if I say that the parasite of malaria is a much more difficult subject of study than the tubercle bacillus. I do not think anyone will add much to our knowledge of the parasite of malaria who is not a trained pathologist and has had long experience in the study of blood, whose routine duties do not leave him time for original work, as well as the opportunity of examining

Digitized by Google

patients, and who is not skilled in the use of very high powers of the microscope. These form a combination of qualities which will never be found largely represented in the members of the medical profession in any country. I believe the best thing that could be done in the present circumstances would be to send a selection of the young men chosen for the Indian Medical Service for six months to Rome or Catania, where they would not only get plenty of cases for continuous study, but would have the assistance of teachers trained in general pathology as well as specially expert as regards the parasite of malaria. Better still, perhaps, would be three months at Catania and three months at Rome, the best season at each being chosen. These men when sent to India could be specially attached to the medical schools of the large cities, charged with the duty of investigating the whole subject of malaria and of teaching the *technique* required by practitioners for diagnostic purposes. If a measure of this kind were carried through there is every reason to believe that India would in time contribute its quota to the furthering our knowledge of the disease in which, of all others, it has the greatest interest.

Queen Anne-street, W.

THE VACCINATION LAWS.

By JOHN C. McVAIL, M.D., D.P.H.,
MEDICAL OFFICER OF HEALTH OF THE COUNTIES OF STIRLING AND DUMBARTON.

JENNER performed his first vaccination on May 14th, 1796. The centenary of this event has been the subject of national celebration at St. Petersburg. In Berlin, the capital of a country in which vaccination and revaccination are practically universal and small-pox practically non-existent, Virchow and Koch and Von Bergmann and other men of world-wide reputation have held a great gathering in honour of a "benefactor of the universe." In Jenner's own country the circumstances are different. A Royal Commission on Vaccination has been in existence for nearly seven years and has not yet reported, the delay, it may safely be assumed, being due to the determination of the Commissioners to do their work thoroughly when they are at it. Compulsory vaccination in England has, however, in the meantime become a matter of local option, and in an increasing number of places the option, as expressed in the election of boards of guardians, is taking the form of non-compulsion. The growing neglect of vaccination in England is roughly indicated by the returns published annually by the Medical Department of the Local Government Board. The percentage of cases "not accounted for"—that is, infants who have neither been vaccinated nor died—was in 1872 8·8 in London and 4·5 in the rest of England. For London low-water mark was reached in 1881, when only 5 7 per cent. were not accounted for. For the rest of England the lowest year was 1875, when the percentage not accounted for was only 3 8. By 1888 the London and "rest of England" percentages had reached 10 3 and 8·2 per cent. respectively, and by 1891 (the latest year for which the data are available) the default had mounted to 16·4 and 12·9 per cent. respectively. No doubt for more recent years the results are still less satisfactory. These high figures are due mainly to neglect of vaccination in particular localities. In many places there is practically no omission to vaccinate, and such percentages as 0·0, 0·1, and 0 4 are not unknown. But in Gloucester the "not accounted for" were in 1891 no less than 84 per cent. of the total, in Keighley 83, in Leicester and Northampton 80, in Oldham 78, in Luton 77, in Kettering 75, and so on. In the metropolitan districts the worst figures are for Mile-end Old Town, 50 per cent.; for Hackney, 40; Bethnal Green, 38; Poplar, Greenwich, and Stepney, 19; and Paddington, Camberwell, and Westminster, 17. It is not my present purpose to discuss the value of vaccination and revaccination. I believe that vaccination is of essential importance as a preventive of small-pox, and that perhaps no greater physical boon than the Jennerian prophylactic has ever been conferred on humanity. It is from this standpoint that the question of the vaccination laws is here viewed.

These laws are at present utterly unsatisfactory. Though called compulsory they do not compel. At the most they offer a choice between submission to vaccination on the one hand and payment of a money penalty on the other. The enforcement of this choice is in the hands of boards of guardians, whose practice is anything but uniform. While one board insists on prosecutions and fines repeated regarding the same unvaccinated child so long and so often as a fixed age limit permits, an adjoining board may be satisfied with a single prosecution, and yet another may absolutely decline to take any action, while every election of guardians may suddenly reverse whatever custom has previously prevailed in the district. Elections *ad hoc* with all their recognised disadvantages are not infrequent. It thus results that the option to refuse vaccination without prosecution or penalty is not that of the individual, but that of the electoral division in which he resides, while if there is to be any option at all it obviously ought to be personal and not collective. Nor in districts where penalties are inflicted is the choice given between submission and penalty naturally a fair one, as the maximum fine, while bearing heavily on the agricultural labourer, is a trifle in the case of the well-to-do. Cheap martyrdom has temptations for many minds, and the vaccination laws present the opportunity for the desired notoriety. The fine imposed, however trifling, is not paid, imprisonment follows, and the subsequent release is celebrated by music from the local brass band, a demonstration, stump speeches, and a presentation. Carried away by the influence of what Carlyle, speaking Teutonically, calls "swarmery," such scenes result in the wholesale manufacture of anti-vaccination sentiment.

Another defect in the present law is that it says nothing whatever as to the thoroughness of the vaccinal operation. No fact in medical science is better attested than that the amount of protection depends largely on the sufficiency of the protective procedure. Every small-pox hospital bears witness to this, and the evidence applies to every period of life. In illustration it may be recalled that Dr. Gayton, who treated over 10,000 cases of small-pox in the metropolitan hospitals, found that in patients under fifteen years of age 706 who had "good marks" of vaccination had only 7 deaths among them, or less than 1 per cent.; while 2192 who had "bad marks," or though alleged to be vaccinated showed no marks at all, had 209 deaths among them, or over 9 per cent. Among 1504 cases admittedly unvaccinated at the same ages the deaths were 639, or 42 per cent. The amended law should provide that whoever is vaccinated should be sufficiently vaccinated. No mere sham vaccination ought to be any longer possible to swell the ranks of those who, though registered as protected, are ready to succumb to the first approach of small-pox infection.

In addition to being both irritating and inefficient the law is utterly illogical. In 1853, when the first compulsory Act was passed, the need for revaccination was not sufficiently known. The recognition of its necessity has, indeed largely grown from the experience of the protective results of infantile vaccination following on the operation of the law of that year. Primary vaccination had previously been performed at any age, but in 1853 the systematic protection of infants was begun, and we now have learned that that protection cannot be relied on to last in full amount throughout the whole of life. And here it may be desirable to note shortly what are the teachings of experience regarding the amount and duration of vaccinal protection. Loss of protection due to a first vaccination varies with varying circumstances. If the operation be performed in infancy then its influence appears to be gradually weakened or diluted by the growth and development of the tissues and increase in bulk of the body. If it be performed later in life, when development is approaching completion or is already complete, its influence is much more lasting. If, therefore, revaccination be desirable, say, at ten years of age, it does not follow that a third and fourth vaccination should be done at twenty and thirty years of age, and so on. In Germany since 1874 vaccination has been compulsory both on males and females in infancy and again at eleven or twelve years of age. On healthy males a third vaccination is performed when they enter the army, but no evidence has yet been produced of excessive prevalence of small-pox among the female population of Germany through their want of a third vaccination. All the same, circumstances may arise—such as exposure to the infection of epidemic small-pox in a given population—rendering a third vaccination a wise precaution in adult life, if the second vaccination has been done a very long time previously. But the mention of ten to twelve years of age as the proper time for a second

Digitized by Google

vaccination is apt to mislead. It is not to be assumed that the influence of infantile vaccination has disappeared by that age. The diminution of protective power is graduated both as to quality and time. The first manifestation of the drift towards small-pox consists in a return of susceptibility to the local effect of vaccination. Immediately after the completion of the vaccinal process there is no reaction to the insertion of vaccine virus. But by-and-bye a successful local vaccination becomes possible, so that it was found in Bordeaux that attempts to revaccinate at six years of age were in 40 out of every 100 children successful in producing the vaccine vesicle. This does not mean that these children were susceptible to infection of small-pox in the ordinary way. In the Sheffield epidemic of 1887 in houses actually invaded by small-pox, and where the activity of the small-pox poison was manifested by the fact that about 90 per cent. of unvaccinated inmates were seized by the disease, it was found that among the vaccinated inmates of the same houses the attacks between ten and fifteen years of age were not 98 per cent., as in the unvaccinated inmates at that age, but only 25 per cent.; and between five and ten years of age not 92 per cent., as in the unvaccinated at that age, but less than 10 per cent. Thus susceptibility of the vaccinated to attack by small-pox returns at a later age than does susceptibility to the local effects of the vaccinal operation. But this is not all, for resistance of the vaccinated to *death* by small-pox outlasts very considerably resistance to *attack* by small-pox. At Sheffield under twenty years of age the percentage of deaths to attacks among the vaccinated ranged from 0·8 to 2·2; between twenty and thirty years the percentage was 5·4; and it was only over thirty years that the deaths reached 10·6 per cent. of the attacks. Yet such percentages both of attacks and deaths furnish abundant evidence of the need for revaccination. The liability of 25 per cent. of persons over ten years of age to be attacked, and the further liability of a small fraction of this 25 per cent. to die from small-pox, make the age of from ten to twelve years a proper time during which to renew the protection. I repeat, therefore, that the present law is utterly illogical in so far as it takes no cognisance of the need for revaccination. The protection of adults is as important as the protection of children, and whatever degree of insistence should be maintained in respect of infantile vaccination should also be maintained in respect of revaccination.

What degree of insistence ought to be maintained? That, no doubt, is one of the principal questions, if not the principal question, before the Royal Commission. The object of the Legislature should be to get as many persons as possible as well vaccinated as possible. That object, however, should be carried out in accordance with the spirit which governs present-day legislation in England. Russian methods are not for these realms, and the ways of the twentieth century will not be those of the tenth. There is even a difference since 1853, when the first obligatory enactment was passed. In this connexion due weight, but not more than due weight, must be given to the existing opposition to vaccination in many parts of the country. As regards compulsory vaccinal legislation, it is beside the point to argue that the anti-vaccination movement is carried on mainly by cranks, and that the public is simply being gulled by their persistent misrepresentations and mis-statements. All that, and much more, may easily be granted without altering the hard fact that a very appreciable number of people have been misled into doubting or denying the value of vaccination, and into the fear that vaccination may cause all kinds of unknown evils to their children. A still larger number of persons, while not themselves objecting to vaccination, object to the prosecution and penalising of their neighbours who have "conscientious objections" to the operation. In quite a number of localities, as has already been indicated, the law is at present a dead letter, and in at least a few of these it is probable that it could not be generally brought into operation again excepting by forcibly taking the child from the mother's arms and vaccinating the child in spite of her protests. It goes without saying that this course is repugnant to all present-day notions, and is in itself altogether objectionable.

The law, therefore, must allow some degree of option. How little and how much? *In limine*, a clear distinction must be drawn between the conscientious objector and the parent who is merely indifferent. The former, utterly wrong though he be, must have his scruples yielded to. On his behalf, and in the best interests of vaccination itself, I would abolish, not only imprisonment for unpaid fines, not only repeated prosecutions and penalties, but all prosecutions and penalties whatsoever directed against any man for refusal to allow vaccination of those for whom he is responsible. But what is to become of the protection of children whose parents are merely indifferent, to whom the whole question is the trouble, first of making up their minds to do a particular thing on a particular day and then of carrying out their intention so formed? For them, and also incidentally for the conscientious objector, the inconvenience attending on refusal of vaccination must be made at least as great as the inconvenience of going to the station for vaccination and a week later going a second time to have the vaccinated arm inspected. A national register of the unvaccinated should be established, and in order to get a name entered in this register the parent or guardian should have to go personally to a magistrate and make a sworn affidavit of his conscientious objection to vaccination. Having got a certificate from the magistrate he should then have to go personally to the registrar's office to have the necessary entry made there. No doubt the whole procedure could be made so elaborate as to be no less troublesome than that involved in the vaccination itself. It may be suggested here that a registration fee should also have to be paid, but this might be looked on as a fine, and my own view is that money fines for "conscientious objection" should be abolished.

Several advantages would belong to some such system as this: (*a*) It would be possible to enact that if vaccination were to be done at all it would have to be sufficiently done. There would be no hardship in insisting on a given number of insertions or of a given area of insertion when every parent would have the right of declining vaccination altogether. (*b*) The result would be that those who were themselves thoroughly protected would have no cause for fear from small-pox among the unvaccinated. At present there is in the presence of small-pox constant anxiety as to the risks of children who have been only imperfectly and insufficiently vaccinated. (*c*) The different behaviour of small-pox as between the vaccinated and the unvaccinated would, as a consequence of the increased efficiency of the vaccinations and of the registration of the unvaccinated, be demonstrated even more clearly than at present, and statistics on a national scale would soon be available for the consideration of conscientious objectors whose judgment might be capable of being influenced by facts. (*d*) The supply of martyrs in the cause of anti-vaccination would cease. No satisfactory amount of local indignation and enthusiasm could be got up for a parent whose worst hardship would consist in the infliction of a fine for his refusal to call on a magistrate and a registrar to get his conscientious objections recorded. I do not suggest that all the leaders of the agitation would be either satisfied or silenced; but the opposition to vaccination, fanned as it is by tales of martyrdom and by the whole system of prosecutions and penalties for non-vaccination, would largely die out in spite of all efforts to maintain it. (*e*) But another consideration, much more important than any of these, remains to be adduced. Compulsion being abolished, the above-described alternative of vaccination, or registration of non-vaccination, could and should be made universally applicable, not only to infants, but also at ten or twelve years of age. In this way a national system of revaccination would be established on exactly the same lines as the proposed system of infantile vaccination. Whether an infant had been originally vaccinated or registered as unvaccinated, the law ought again to come into operation on the child reaching the age of, say, twelve years. If the child had been primarily vaccinated the option would now be between revaccination on the one hand and registration of conscientious objection to revaccination on the other. If the child had been originally registered as unvaccinated the parent or guardian would now require to make the choice between primary vaccination of the child of twelve and renewed registration of conscientious objection. The ultimate effect of this renewed offer would be to add immensely to the total amount of vaccinal protection in this country, and I am inclined to believe that the gain in revaccination would more than atone for any diminution in primary vaccination which might be a first effect of alteration of the present law. However that may be, the new law would at least be logical in recognising the fact that revaccination is a necessity in addition to primary vaccination. At present there are hundreds of thousands of persons in this country who have a "pious opinion" that revaccination is an essential precaution

Digitized by Google

against small-pox. But the precaution is delayed indefinitely owing to its never being brought before them as a duty requiring immediate performance. Under the system as here set forth this off-putting would come to an end. One administrative difficulty suggests itself as to this scheme—namely, the ascertaining of the exact time of each child's reaching the age for revaccination. How this is done in Germany I do not know, but with the aid of school boards and of the census (which, by the way, ought to be quinquennial and not decennial) there should be no insuperable obstacle. There is yet another set of circumstances in which the law should again interfere to obtain, with regard to unvaccinated and unrevaccinated persons, either a declaration of conscientious objection or submission to the protective operation. When small-pox threatens to become epidemic in any community the Local Government Board should have power to issue an order bringing into force this provision of the suggested Vaccination Act, and it is certain that great benefit would result. In any large city where agitation against vaccination has been active and effective, at any given date there might be found even under the new law a large number of children who had been registered as unvaccinated, and a large number of persons over twelve years old who had been registered as unrevaccinated. It may be urged that in the case of a local epidemic of small-pox even under the new law there should be a resort to penalties for non-vaccination, and that here at least it would be the bounden duty of the State to compel the operation. That is a view from which, on the whole, I would dissent. Having once adopted the principle that there should be no money penalties for non-vaccination the principle should be adhered to. But the fact is that in the presence of actual small-pox "conscientious objections" are apt to be set aside, and many parents would not care to take the responsibility of again refusing on behalf of their offspring the proffered protection. With regard to such persons it is easy to say, "Serve them right; let them get the small-pox"; but the object of the State must be to afford protection wherever it will be accepted, even to those who, in the absence of the bane, have declared their disbelief in the antidote. And always it has to keep in view that the main sufferers from anti-vaccination are the little children, the helpless victims of the wrong-headedness of their parents. In a stricken community the offer of vaccination would not of course be withheld even from adults who already, both in infancy and at twelve years of age, had undergone the operation.

In revising the vaccination laws it is important that everything possible should be done to allay fears as to possible evil consequences from the operation. In England the total number of births in any year is about 900,000 and the number of deaths from all causes under one year old is about 140 for every 1000 births, or, in other words, of 1000 children born only 860 reach one year of age. The mortality is greatest of all in the first months of life. The age fixed by law for vaccination in England is under three months, and as the vaccinal process, dating from the operation to the fall of the crust, occupies about three weeks, it is obvious that a considerable number of deaths from ordinary infantile ailments must occur "under vaccination," and it may be assumed that, at least in places where there is an organised opposition, in the case of many of these deaths vaccination has to act as the scapegoat. That will be the case to some extent no matter at what age the operation is performed, but there is no reasonable doubt that vaccination would be less blamed if the operation were deferred until death had done its work among the weakly and ailing under one year of age. Among the survivors most of the cases of skin eruption due to dentition would by that time have developed themselves, so that here, too, the *post hoc propter hoc* argument of vaccinal origin of such cases would not be available. In Scotland the vaccination age is six months, not three months, as in England, and there certainly is much less opposition to vaccination in the northern kingdom, though to what extent the age question is a factor here it is difficult to say. Anyhow, there is a sentimental objection to operating on babies a few weeks old, and I am of opinion that vaccination should not be insisted on until the child is about to complete its first year. In presence of small-pox, however, the Local Government Board should have power to issue in any locality an order fixing the compulsory age at three months or six months. In Germany the operation has to be done during the first calendar year following the birth of the child. Thus a child born any time between Jan. 1st and Dec. 31st, 1896, must be vaccinated some time between Jan. 1st and Dec. 31st, 1897, so that the average age is probably a little under eighteen months.

While there is nothing of any importance that human beings can do which is absolutely without risk of some sort, vaccination is yet an exceedingly safe proceeding. Taking all the death registrations in which it is mentioned as having any part in the matter (and in many of such cases it is a mere incident), there are not much more than one-twentieth of the deaths set down to it that are set down to the suffocation of children by bedclothes. Nevertheless, as a result mainly of an active propaganda, vaccination has in some districts to bear the blame of many of the ailments which befall children in the course of their ordinary upbringing. There is in the minds of some people an impression that "humanised" lymph is apt to convey all kinds of diseases from the vaccinifer to the vaccinee. Among medical men no such fear prevails, and in their own families they no not hesitate to use lymph taken from a healthy child. But there is no reason why consideration should be refused even to this ill-founded fear. In calf-lymph we have an inoculative material at least equally safe (theoretically even safer) and not necessarily less convenient. On the Continent (where probably arm-to-arm vaccination was not performed with the same care and caution as in this country) calf lymph is now almost universally used. It is quite free from one particular risk, which though almost infinitely unlikely of realisation is yet most serious when realised. In one respect calf lymph possesses a great advantage over arm-to-arm lymph; in emergency it is capable of indefinite multiplication, so that material for the vaccination of a whole city can be prepared within a very short time by the simple expedient of vaccinating from one or two calves as many more calves as may be required for the purpose. With humanised lymph this is impossible, as the whole stock obtainable on any one day from the largest vaccination station in the kingdom would suffice for only a very limited number of fresh operations. In an epidemic, moreover, many of the vaccinees are adults and these should never be used as vaccinifers. When this question of the substitution of calf lymph for humanised lymph was first raised in England it was objected that a considerable proportion of the insertions of calf lymph would fail in producing proper vaccine vesicles—that the insertion-success would not be so great as in arm-to-arm vaccination. So far as calf lymph is concerned this fear has been found groundless. An experienced vaccinator can produce good vesicles up to within a fraction per cent. of his insertions. With stored calf lymph, however, the success is probably not so great. On the other hand, it is urged in favour of preserved calf lymph that the glycerin with which it is commonly mixed has the effect of destroying extraneous infection, such as that of erysipelas, which is about the only genuine risk that ever really does accompany vaccination, and, rare as is serious vaccinal erysipelas, it is yet very important that so far as may be it should be avoided. The point is one on which I do not venture to express an opinion, but no doubt the comparative merits of fresh calf lymph and stored calf lymph will be considered by the Royal Commission. In France fresh calf lymph is used, and it is held there that careful antiseptic precautions have left no fear or risk of erysipelas. If this be so then probably fresh lymph ought to be selected. In the French vaccination system the vaccinator proceeds from village to village, previous public intimation having been given of his itinerary. The calf to be used is conveyed in a specially constructed vehicle and the lymph is applied directly from calf to arm.

By what machinery could such a scheme of national vaccination as is here advocated be carried out? At present in Scotland, unless for certain exceptions in some of the largest cities, every medical man vaccinates the children within his own practice, and as a family medical man is selected on account of the confidence which is felt in his skill there is much less tendency to rush to *post hoc* conclusions than in England, where from one-half to two-thirds of the vaccinations are done by public vaccinators specially appointed. Yet if calf lymph were to be generally adopted it would be a matter of practical necessity that in any calf-to-arm system the work should be done by medical men specially appointed and even confined to vaccination duty. At present in England the local authority in charge of public vaccination and public vaccinators is the board of guardians. This is an anomaly which ought to be remedied. Vaccination is a public health provision and ought to be

Digitized by Google

under the charge of a public health board. When small-pox prevails it is absurd that the authority which has charge of hospital arrangements, disinfection, &c., should have to go hat in hand to the Poor-law guardians with regard to increase of facilities for vaccination, especially as the two bodies do not always see eye to eye on so essential a preventive measure. But as to the authority which ought to supply the calf lymph I am not quite so clear. It is out of the question that every public health department, urban and rural, should maintain a calf lymph establishment of its own. The duty ought to be entrusted to the Local Government Board or to the county councils, and the experience of foreign countries will be available to the Commission in deciding which course would be the more efficacious and the more economical. Personally, I would be inclined to place the responsibility as high up as possible—with the Whitehall Board rather than with county councils; but it is conceivable that there might be practical difficulties with regard to the transportation to remote districts of vaccinated calves. English counties are of such diverse areas and population that they do not strike one as suitable administrative units for such a purpose. No doubt combination of counties could be made, but joint boards are not free from objection, and the whole country might as easily be divided into large districts for central administration as grouped into counties for joint county government. Even under the latter arrangement there would have to be supervision from Whitehall, and I see no sufficient reason why Whitehall should not take charge of the whole business. The question, however, is for consideration by the Commission, which has at its disposal all available sources of information.

Such is the general scheme of legislation which seems to me best suited to meet the circumstances of the present time in this country. It would do away with all the irritation and ill-feeling consequent on prosecutions and fines, single or repeated, for neglect of vaccination; it would provide in the case of those who have conscientious objections a national register of the unvaccinated; it would at the same time be designed to prevent non-vaccination as a result of mere parental indifference; it would offer calf lymph to all who might choose to have it; it would (subject to the option of the register) provide for revaccination at twelve years of age and also in presence of epidemics in particular communities; it would insist that vaccination when done at all should be efficiently done; and it would postpone to twelve months the age at which primary vaccination should be formally demanded. Against this scheme it may be urged that its first and immediate effect might be to produce a diminution in the amount of infantile vaccination. This would be easier to urge than to establish, for it is to be kept in view that in many places at present where boards of guardians take no action no definite pressure is brought to bear on the merely indifferent. It is not to be supposed that in Gloucester, Keighley, Leicester, Northampton, &c., 80 per cent. of the population are conscientious objectors, and great part of the neglect is no doubt due to sheer carelessness or to the fashion of the locality. Possibly, however, taking the country as a whole, the fear might be realised that there would be, as a first result of the new law, some diminution in the amount of infantile vaccination with, as a result, recrudescence of small-pox and loss of lives which vaccination would have saved—lives mainly of helpless children suffering death for the folly of their parents. But the fact must be faced that even at present, material is accumulating for a small-pox epidemic and it almost looks as if the death toll were already beginning to be exacted. The further fact must be faced that owing to a combination of causes which have been already indicated there has been arising in this country a considerable amount of prejudice against the present vaccination laws. There is a deliverance of Burke which has been already quoted by a foremost opponent of vaccination and which will bear requotation here: "It would be dreadful indeed if there were any power in the nation capable of resisting its unanimous desire or even the desire of any very great and decided majority of the people. The people may be deceived in their choice of an object; but I can scarcely conceive any choice they can make to be so very mischievous as the existence of any force capable of resisting it." It is hard to say exactly where Burke would have drawn the line in regard to the present question. Where does the duty of the State end to enforce on children what it believes to be an important sanitary measure, and where does the right of the parent with conscientious objections begin, to refuse to submit his child to what he supposes may be a very dangerous proceeding? We have had compulsory education since Burke's day, and I do not for a moment believe that the majority of the people are opposed to vaccination, but I do believe that the opposition has become so considerable that it would be unwise to attempt universal enforcement of vaccination. If it is too much to hope that the operation of the scheme sketched in this article would not diminish infantile vaccination (and even that hope I would not care to abandon until the scheme had been tried), it is at least a reasonable expectation that revaccination would be much more largely resorted to than heretofore, and that loss of child life might in the national economy be compensated for by saving of adult life. And though it is a hard thing to say, the prevalence of small-pox in the young would have this beneficial effect, that it would educate the parents of this generation into an acquaintance with, and a horror of, small-pox which are almost unknown nowadays owing to the very success of the Jennerian prophylaxis. The ultimate result might therefore be that vaccination would once more become almost universal and that revaccination would obtain a prevalence which it never has yet possessed in these realms.

Perhaps, before closing this article, I should refer to a proposal which is coming to be more and more mentioned in connexion with the prevention of small-pox—namely, compulsory hospital isolation. Let it be observed, in the first place, that this, though it would be a most useful adjunct to any incomplete and partial system of national vaccination, could never become a substitute for vaccination. Even putting aside the known fact that small-pox hospitals have often themselves proved centres of infection to surrounding unprotected populations, it is obvious that such a hospital requires a staff of attendants, and that these, if not themselves protected, would fall victims to infection, and that they in their turn would require another staff of attendants, and so on indefinitely; but if it be urged that in the absence of vaccination there would be no lack of surviving small-pox-protected nurses, I have no word to say in reply; of patients, at any rate, there certainly would by-and-bye be a superabundance. Let it be observed, in the second place, that the compulsion of universal hospital isolation would soon raise up against it the same outcry that has accompanied compulsory vaccination. Already, as the results of attempts at this method of prevention in ill-vaccinated neighbourhoods, we read of the burning down or other destructive injury by infuriated mobs of two intended small-pox hospitals in the West of England. And if the system of compulsory isolation which is at present only tentatively resorted to were formally established by law it would have directed against it all the artillery of anti-compulsion. Already some of the leaders of the anti-vaccination movement do not hesitate to state that their opposition to the one scheme would be as active as to the other. If, then, it be suggested that optional removal to hospital should be followed as a system of small-pox prevention, where do we land ourselves? Supposing that ninety go to hospital and ten stay at home, the ten will soon be surrounded by ninety more, and the ninety by nine hundred, and so on indefinitely. There would be no protection for anybody, while optional vaccination has at least the advantage that it protects those who choose to accept protection. The wise in the community must, therefore, in the meantime be satisfied with thorough protection of themselves and their offspring, and with doing their best to teach the truth about vaccination to their deluded neighbours, at the same time that the Legislature continues to bring to bear on the population at large such pressure as shall be most likely to produce, with regard both to vaccination and revaccination, a maximum of result with a minimum of friction. This is not a heroic remedy. Perhaps it is mere opportunism; but I believe that in the end it will most nearly fulfil the desideratum with which I set out, that in this country there should be as many people as possible as well vaccinated as possible.

EAST LONDON CHILDREN'S HOSPITAL.—The anniversary dinner of the East London Hospital for Children was held on May 13th, at the Hôtel Cecil. Mr. John Aird, M.P., presided. Cardinal Vaughan, in proposing the toast of "The Board of Management," said he was specially indebted to this hospital, all his clergy testifying to the great benefits it conferred on their extremely poor people. Donations amounting to £1240 were announced, including 100 guineas from the City Corporation.

ON AN

INTERESTING ANOMALY OF THE OCULAR MUSCLES: A CLINICAL STUDY.[1]

BY W. ERNEST THOMSON, M.A., M.D. EDIN.,

MEDICAL OFFICER TO THE EYE DEPARTMENT OF THE GLASGOW PUBLIC DISPENSARY AND CLINICAL ASSISTANT TO THE GLASGOW EYE INFIRMARY.

THE case forming the basis of this communication is a marked example of a class not really very rare in its less pronounced forms, which has not hitherto received much attention from ophthalmic surgeons generally, although it has been most carefully investigated and described by Dr. G. T. Stevens of New York.[2] I refer to that class of anomaly in which there is a tendency to deviate, or an actual turning of one visual line from the other in a vertical, or in a combined vertical and horizontal direction. It is no part of my purpose to explain Dr. Stevens' papers. They explain themselves in the clearest possible manner. But it may be well, in order to avoid repetition, to refer to his classification of the anomalies of the ocular muscles.

Orthophoria means a tending of the visual lines in the correct direction. Since the terminology is based upon the positions of the visual lines in distant fixation (under which condition they are normally parallel), orthophoria means that the visual lines remain parallel on distant fixation, even though binocular single vision be abolished by screening one eye, or rendered useless by destroying the similarity of the images received by the two retinæ.

Heterophoria means a tending in some other direction. It means that under ordinary conditions, when both eyes are directed to a distant point, the visual lines habitually remain parallel; but that when one eye is screened, or binocular single vision is rendered useless or impossible, the visual lines tend to take up some position other than that of parallelism. Under ordinary conditions parallelism is maintained, but with difficulty. When the conditions of vision cease to be ordinary the visual lines cease to be parallel.

Heterophoria is subdivided into—esophoria, a tending of the visual lines inward; exophoria, a tending of the visual lines outward; and hyperphoria, a tending of one visual line in a direction above the other (right or left hyperphoria).

Strabismus is called heterotropia, which means a turning in some direction other than that of parallelism; but the line between occasional heterotropia on the one hand and heterophoria on the other is not a hard and fast one. Heterotropia is similarly subdivided into esotropia, exotropia, and hypertropia—inward, outward, and vertical strabismus. Deviations or tendencies which are partly lateral and partly vertical are named hyperesotropia, hyperexotropia, and hyperesophoria, hyperexophoria—right or left, as the case may be.

The patient, a man aged thirty years, who consulted me first in November, 1895, complained of defective sight since boyhood, gradually becoming worse; of headache, of inability to read for any length of time, and of some difficulty in seeing at night. On examination ophthalmoscopically there was found to be compound myopic astigmatism which admitted of the following correction: Right – 1·25 D sph.◯— 2 D cyl. axis 175° V = ⅓; left – 4 D sph.◯—1·75 D cyl. axis 35° V = ⅓. The fundus was apparently healthy except for a moderate degree of staphyloma posticum. But before estimating the refraction I had observed the peculiar fact that the right optic disc was unusually high up and the left unusually low down in the direct ophthalmoscopic picture, and had made the provisional diagnosis of vertical error. Following up this clue—1. The patient, an intelligent, observant man, states that when reading his evening paper, if an illustration occur in the text below and to the right of the line which he is reading, that illustration sometimes floats upwards and to the left and becomes superimposed on the print to which his attention is directed, so that he sees the print through the illustration; this statement exactly tallies with the undoubted fact that he reads with the more myopic left eye and allows the right eye to rotate downwards and to the right. 2. If the right eye be covered while the left fixes a spot of light at some distance (in this case barely 5 metres, the width of the consulting-room), this right eye rotates downwards and slightly to the right, readjusting upwards and to the left when the cover is removed, provided that the patient be stimulated to make an effort at fixation. If not so stimulated the eye sometimes remains in its faulty position until some new movement of the eyes is required. If the left eye be covered while the right fixes, this left eye rotates upwards and slightly to the left and readjusts on removing the cover. 3. An actual strabismus, chiefly vertical, can sometimes, but not by any means always, be detected on inspection. The deviation varies according to the distance of the fixation point and the consequent choice of one or other eye for fixing. 4. If, while an effort at binocular distant fixation is made, the ophthalmoscope be quickly slipped in front of one eye it is quite easy to watch the optic disc rotating, the right upwards and the left downwards, to the position of rest. The lateral movement is much less obvious.

Early in the investigation it became apparent, as indicated by the statement about the illustration, that binocular fixation at near points either does not exist or exists only momentarily. There is, however, a question raised by the above-mentioned four points—namely, Does binocular fixation exist at all, even for distance? If it does, is such fixation habitual? If not habitual, is squinting the rule or the exception? The determination of these questions is necessary in order to exactly name the condition with which we are dealing. The diplopia tests lead one to the answer: 1. The room having been darkened except for a single distant spot of light which the patient fixes, a red glass is quickly slipped in front of the right eye and accurate observation of the result requested. The reply is that he notices a red spot (false image) which appears almost instantly to start from the white spot (true image) and moves upwards and to the left. Similarly, with the red glass before the left eye the red spot jumps away downwards and to the right. 2. It is sometimes possible to make the patient conscious of two spots without the aid of the red glass. He then fuses them by an effort which does not seem to continue long, confusion begins, he winks and rubs the eyes, then makes a fresh effort. 3. Using the Maddox rod and tangent scale the following amounts of deviation are ascertainable. The vertical deviation is very great, varying on different days from 7° to 10° (actual deviation, not prism). Similarly, the horizontal deviation varies on different days from 2° to 6° (outwards). The horizontal and vertical deviations vary in the same sense; on one occasion the horizontal was 2·5° and the vertical 7°; on another occasion the maxima were obtained as horizontal 6° and vertical 10°. The readings are equal whichever eye be under observation. In these diplopia tests the wearing of the correcting glasses does not materially affect the amount of error. In the spot tests, since the left eye is myopic 4D, they must be worn in order to properly bring out the diplopia.

The question regarding binocular vision may now be put in the following form: Is it possible that a person whose visual lines in distant fixation tend to deviate from parallelism 10° in the vertical and 6° in the horizontal direction, in whom, further, the mere red colouration of one retinal image is sufficient to abolish binocular single vision, can, as a rule, have such binocular vision? I think, with Dr. Stevens, that such a high vertical error excludes habitual binocular fixation and makes even its occasional accomplishment, as in this case, somewhat paradoxical.

Before stating the conclusions drawn from the ascertained facts it may be interesting in view of treatment to study the muscles involved. It is obvious that here, as contrasted with the comparatively common combination of horizontal and vertical error, where the principal deviation is horizontal the vertical error is the one which chiefly claims attention. Exophoria is a common condition generally known under the titles "insufficiency of the internal recti," "insufficiency of convergence," and "latent divergence," and one is justified in stating as a result of the diplopia tests that such want of equilibration between the convergence muscles and their antagonists, the externi, exists here in combination with a vertical want of balance between opposing groups of still higher degree. In studying the vertical error one may assume, for simplicity's sake, that an actual strabismus exists. The strabismus is concomitant, for the disturbance of equilibrium is shared by

[1] A paper read at a meeting of the Glasgow Medico-Chirurgical Society, January, 1896.

Digitized by Google

both eyes equally. The excess of elevating power relative to the plane of fixation which is due to some mechanical advantage of the elevators of the upward turning left eye over their antagonists is immediately transferable, when a call for fixation is made on the left eye, in an equal degree to the depressors of the right eye. It might be said with equal truth that the excess of depressing power of the depressors of the downward turning right eye is transferred, when the right eye is called upon for fixation, to the elevators of the left eye; but since, as a matter of fact, the left eye is always (save under the exceptional circumstances when the visual lines are parallel) on a higher level than the right, it is convenient to speak of the condition as a left deviation upwards rather than as a right deviation downwards, which would necessitate the use of another prefix "hypo."

Next one comes to the actual muscles involved in the vertical deviation. The left superior rectus and inferior oblique (elevators of the left eye) possess, relatively to their antagonists, a static advantage of some kind over their associates, the right inferior oblique and superior rectus (elevators of the right eye), consequently an equal nerve impulse to both eyes causes a greater result—i.e., greater elevation of the left eye, the right fixing. It might with equal truth be said, when the left eye fixes, that the right inferior rectus and superior oblique (depressors of the right eye) have, relatively to their antagonists, a static advantage over their associates, the left superior oblique and inferior rectus (depressors of the left eye), and that an equal nerve impulse gives a greater result, greater depression of the right eye.

It can now be understood that when the patient succeeds in fixing a distant spot of light binocularly he does so through an extraordinary effort on the part of the less advantageously situated muscles of both eyes—that is to say, while the right superior rectus and inferior oblique oppose an unusual amount of resistance to the right superior oblique and inferior rectus and for a time prevent this eye rolling downwards, at the same time the left inferior rectus and superior oblique oppose an unusual resistance to the left inferior oblique and superior rectus and prevent this eye from rolling upwards. Parallelism is thus maintained until fatigue overtakes the weaker muscles, or the desire for fusion is lessened or destroyed by altering the appearance of the images or occluding one eye.

I may now summarise the case. 1. There is sometimes binocular single vision for distance. At other times, probably more often than not, there is diplopia with mental suppression of one image, but the deviation is not maximal. 2. In near vision there is always diplopia, usually with suppression of one image; but when a conspicuous object casts its image on the deviating macula the two totally dissimilar images may be superposed and cause confusion. 3. The deviation is concomitant. 4. In distant fixation the left eye tends to turn, or actually turns to a greater or less degree, upwards and outwards, while the right eye fixes. 5. In reading and near work the more myopic left eye is preferred and the right deviates. 6. The condition may be called left hyperexotropia, with the proviso that orthotropia (correct turning as contrasted with orthophoria, correct tendency) is possible at times. It is worth remarking that on certain occasions the error is less in degree than on others, the variation being probably due to variations of the nervous system as to fatigue.

Treatment. — There seem to be four courses open in such a case as this: to do nothing, to shade the right eye when reading, to correct with prisms, and to operate. The two first are, of course, unsatisfactory. The third, though apparently feasible, is not really so, because the weight of the necessary prisms, the colour disturbances produced by them, and the increase of deviation likely to follow their use make them quite impracticable. Even comparatively low prisms lent to the patient for trial proved a source of annoyance and seemed to have no beneficial effect. Of the four courses probably by far the best is that introduced systematically by Dr. Stevens—namely, graduated tenotomy of the superior rectus of the upward turning eye. Then in this case when the vertical error had been removed it would have been necessary to consider the question of operation on the lateral muscles. This is the treatment I proposed. It was rejected, however, and the patient is content at present to go through life with two eyes which, when corrected as to refraction, have fair acuity, but are incapable of working harmoniously together.

Glasgow.

THE TOXINE THEORY OF SYPHILIS.

By ARTHUR H. WARD, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, LONDON LOCK HOSPITAL; SURGICAL REGISTRAR TO ST. GEORGE'S HOSPITAL.

(*Concluded from p. 1348.*)

IN my last paper I brought my consideration of syphilis in the light of the toxine theory up to the dying away of the first outbreak of secondaries. I arrived at the conclusion that the leucocytes must attain a measure of toleration and so be able to encapsule the invading microbes. There appear now to be three courses open: the cells may sooner or later utterly destroy the microbes and end the disease; they may be unable to restrain them, and recurrent outbreaks occur with the production of larger and deeper lesions, profound anæmia, asthenia, and death; or an intermediate course may be imagined, in which the semi-tolerant cells may prove to be such an unfavourable environment that the microbes will enter the spore state. In the first case the total destruction of the infection will rarely follow the first general outbreak even in the most resistant individuals. Here and there local outbreaks, "reminders," will occur, often to be attributed to local depressing causes, such as friction of a rough vest, shampooing, the growth of other microbes in the mouth or tonsils, irritation of the hands in working people, the irritation of hat-linings or neglect of the scalp. Even in a case under treatment I have seen an acute and extensive ecthyma follow semi-starvation in consequence of the unfortunate man falling out of work. This case opened my eyes to the enormous importance of good food. In this class of case under a proper *régime* the local cells will gradually get the upper hand and the lesions disappear. The occurrence of ring-shaped and serpiginous lesions indicates that a local microbic invasion may occur, starting from a centre and growing over a considerable area of tissue, leaving the local cells so resistant that a second invasion of microbes from a neighbouring centre cannot gain foothold. Ultimately the recurrence of lesions ceases, and there is no reason to doubt that in many cases a total extinction of the infection results. It is to be noted that the cases in which the infection is quickly overcome are just the ones in which re-infection occurs. Toleration is quickly acquired and quickly lost, leaving the organism unprotected.

The next class of case, the worst of which are described as galloping or malignant syphilis, are those in which resistance is feeble from idiosyncrasy or some debilitating circumstance. It is interesting to remember that tuberculous people are very susceptible, when the experiments showing acute reaction of syphilitic lesions to the injection of tuberculin are borne in mind. In these malignant cases the toxine tide in the blood apparently never falls and toleration is never acquired, the secondary foci grow larger and larger, and ulcerations with probably local growth of other microbes and septic absorption follow. The eyes and other organs are invaded, infiltration and sloughing of the palate and other parts, with osteitis, necrosis, nervous lesions, and so on, combine with general toxæmia and lardaceous degeneration to kill the patient.

Early lesions involving the brain are generally due to hæmorrhage or thrombosis consequent on the softening of the coats of small arteries from, I suggest, the growth of foci on and through the walls; the coats consequently become permeated with round cells, which collect also outside and inside the vessel. Here they may occlude the lumen and cause thrombosis, or the softened wall may distend into an aneurysm and ultimately burst. Other foci may be established at the foramina of the skull, at which points of terminal circulation microbes may be expected to have been stranded, and here cause pressure symptoms. The iris may be the seat of lesions, with consequent collections of cells forming the plastic exudation, and adhesions may result. The occurrence of foci in the choroid similarly accounts for the circular patches of exudation followed by organisation and atrophy. In this way I would account for all secondary phenomena, special symptoms being due to the anatomical situation of the foci. The occurrence of alopecia I regard as due to foci growing in the scalp, but the general falling of the hair I suggest is due to general toxæmia, as similar conditions follow acute fevers.

In less acute cases the later secondary lesions may grow larger and deeper here and there. At this stage the toxine

Digitized by Google

tide will be fairly low since the local lesions are fewer in number, a corresponding activity of chemotaxic cell infiltration will occur, and consequent overcrowding and disintegration follow. The slow ulceration of rupia will thus result and give an opening to saphrophytic microbes to grow and form absorbable poisonous products. The tongue or the eyes or other regions may be more or less intensely invaded and corresponding lesions produced. The rule seems to be that the fewer the foci the larger the lesion, and the greater the infiltration and tendency to ulceration. Whether the lesions are slight and tend to disappear, or grave and tend to ulcerate, seems to depend on the resisting power of the individual, and this can be increased by treatment and diet or depressed by their absence.

The middle course in which the two forces are evenly balanced can easily be imagined. Here the cells will encapsule the microbes and not be able to destroy their vitality, but will form a sufficiently unfavourable environment to reduce them to the spore state. The tubercle bacillus is also a spore-bearing organism and undergoes this change with caseation. Considering the resemblance between the two toxines and between the granulomatous lesions in the two diseases I see no difficulty in taking this view. It is also the only explanation that can be offered for the occurrence of tertiary lesions, since it seems most unlikely that microbes could remain encapsuled for forty years perhaps, or that if multitudes were so existant that they would not form toxine enough to prevent the patient enjoying perfect health. As spores, however, they would rest inert like particles of pigment in the cells, the production of toxine would cease, and the cells wander away from the foci carrying their burden of spores among the fixed fibrous tissue cells. These would, I imagine, absorb the leucocytes and so receive the spores, or take them up on the death of their original hosts, or these last may become fixed as fibrous tissue cells. In some such way the fixed cells must take up the spores, since it is among them that the tertiary lesions develop. These take the form of gummata or infiltrations, the one tending to disintegrate and the other to organise. In the skin and subcutaneous tissues, where fibrous tissue cells abound and consequently spores would be thickly sown, gummata are the rule, while in the viscera, where the fibrous tissues are more sparse and the blood-supply more free, infiltrations are, perhaps, more common. Gummata, however, are not infrequent and the acuteness of the process must depend, one would think, on the density of the spore infection. These processes, I believe, are identical in essence and strictly analogous to the infiltrations of the primary and secondary lesions.

I suggest that a gumma can form somewhat in this way; some local depression of vitality, often a traumatism, determines the bursting into vitality of one or more spores; these form a colony and form toxine; this toxine as it diffuses depresses the vitality of neighbouring cells, and the spores resting in these awake and form further toxine, this process extending indefinitely in all directions. Chemotaxis naturally following, the focus would become packed with leucocytes, and since again we have a single huge focus the toxine would diffuse freely, and the cells, having lost most of their tolerance, as the possibility of re-infection indicates, would respond as in the case of the primary sore. Hence the induration may again be nearly as dense. At first some attempt at vascularisation, with formation of new vessels, takes place, but later the cells crowding in will be unable to penetrate beyond the vessel walls, the vessels will become blocked with them, and thrombosis be established. The central parts of the gumma will then disintegrate, and an ulcer result presenting the imperfectly fibrosed outer parts of the gumma in the shape of macerated "wash-leather" sloughs. The infiltration of more vascular structures, like the skin or viscera, will occur by a similar process, but since the blood-supply is better fibrosis will follow instead of disintegration. This profuse lighting up of a large area accounts for the extensive cutaneous "lupoid" infiltrations, which may extend over square feet of the surface, with irregular ulceration of the superficial parts. Again, subcutaneous gummata may start at several points, and so form by coalescence the deep serpiginous ulceration so often seen. It is obvious that a very slight cause may in this way start an extensive lesion, just as a spark may start a forest fire. In these tertiary skin lesions there is no tendency to dying down of the process in the centre, as in the decadent late secondary ones, but infiltration progresses till ulceration occurs. Though tending to the circular form at first, the process later becomes more active at one part than another, and very irregular lesions may result. I therefore think that a severely circular lesion is probably a secondary one, produced by peripheral growth of a single colony, fighting against more or less tolerant surroundings, while a tertiary one progresses more irregularly by peripheral lighting up of spores resting in neighbouring cells. The infiltrations of viscera, the nervous system, and bones can all, I suggest, be referred to this process. In the liver, for instance, gummata may alternate with tracts of infiltration, pointing, I suppose, to an unequal distribution of spores. In a case of sporing, I imagine, the process will be more or less universal, since a traumatism establishing a gumma may occur at any point of the body, and the long arm of coincidence could hardly inflict the injury on the one situation where spores were resting. The anatomical structure of the various parts being considered I think that the above process may well explain all tertiary phenomena. The probability of secondary infections of ulcers by other microbes, with consequent septic absorption, must never be forgotten, since many cases of lardaceous disease and nervous degenerations may be partly due to this cause. I have already referred in my paper on Latency to Dr. Weber's observation of a zone of lardaceous change surrounding gummata of the liver. I can well believe that the amount of toxine diffusing from these large foci might cause this as well as more general degeneration with lardaceous change in the intestinal villi, which I have seen cause death at the Lock Hospital. The "quarternary" lesions, nervous degenerations, ataxia, &c., may well be due to prolonged toxine poisoning without any question of microbial local growth, and naturally these are found to resist treatment.

On the question of treatment and the action of drugs I would suggest that mercury as a potent germicide probably acts by depressing the vitality of the microbes, so reducing their toxine-forming powers and allowing the phagocytes more easily to encapsule and destroy them. Even in so virulent an infection as anthrax mercurialised animals resist an otherwise fatal dose. Over-mercurialisation, however, favours the extension of lesions and microbic growth by depressing the vitality of the tissues. Consequently mercury should never be pushed beyond the slightest touching of the gums. The iodides seem to have little effect on the microbes which determine lesions when the treatment is left off. It must act, I suggest, by breaking up or eliminating the toxine, and so removing the chemotaxic irritant which causes the presence of the microbes to be revealed. The infiltrating cells no longer attracted will wander away, the lesions disappear, and the toxine tide fall, while the microbes will remain apparently latent, as they do for nine months in the fœtus under Colles's law, when the toxine escapes into the mother's circulation. The method of treatment by mercury alone in the early stages is therefore reasonable, the more that can be given short of depressing the patient's vitality, the greater the probable effect on the microbes. With the combined treatment the lesions will disappear more rapidly, but the mercury will also be eliminated more or less, consequently there seems to be a risk of lessening its control over the microbes and so running the risk of spore-formation instead of total destruction of the microbes. I think, therefore, that the combined treatment is indicated only when inconvenient lesions have to be got rid of, and that otherwise mercury alone holds out the best chance of cure. That iodide would have any effect on resting spores does not seem likely, and this accounts for the fact that courses of this drug do not remove the tendency to the future formation of gummata. Mercury, however, by permeating the system and creating an unfavourable environment might possibly do so for a time at any rate, but I doubt if it could enable the cells to destroy the spores. A patient the subject of spores thus is an example of the "Once syphilis, always syphilis" dictum. On the other hand I do not see why in the early stages of the infection mercury should not enable the tolerant cells to destroy the depressed microbes totally and so eliminate the disease.

I have already dealt with the question of congenital disease, but I may be allowed to give a short *résumé* to round off this matter. It is admitted that a child may inherit from either or both parents. When the father is the infector microbes or spores must be conveyed with the semen into the cavity of the uterus; as this is protected by epithelium there is no reason why the mother need be infected, nor is she as a rule. The ovum, however, is in a different case, and the microbes

Digitized by Google

growing on the mucosa will invade it and grow with its growth. In such a case the child is born healthy and well developed because the toxine can diffuse into the mother's circulation, where it will cause a degree of toleration sufficient to prevent the child after birth infecting the mother (Colles' law). If the mother is the subject of active syphilis the germ-cell will either convey the microbes and produce an infected ovum, or the toxine in the mother's circulation will diffuse into that of the child. In the first instance the ovum will not be able to get rid of its toxine by diffusion and so be destroyed; in the second, the toxine diffusing from the mother may well be enough to poison the ovum. In either case recently infected mothers rarely give birth to a viable fœtus (Zeissel). If the father is infected also, the chances of the infection and death of the child are increased. If the infection of the mother is not recent, the toxine-tide in her circulation will be lower and the child may eliminate enough toxine to survive. It is then born puny and miserable, with signs of disease, and is an early prey to marked lesions followed by death. In a child infected by the father alone, the mother not being infected, the child is born healthy-looking, but the safety-valve of diffusion is closed, the toxine will accumulate, and in two or three weeks the foci, corresponding to secondaries in the adult, are declared. The after-course of the infection resembles that in the adult, and must depend upon the resisting power of the individual. It may run a malignant course or gradually resolve. Sporing may occur and gummata follow in after years. It seems possible that intra-uterine sporing might occur in a resistant case, and this may account for those exceptional cases in which no symptoms occur in infancy or even up to forty years (Diday). The special affections of interstitial keratitis and internal ear disease may perhaps be accounted for by saying that since the microbes grow in the ovum from the earliest stage they may reach tissues which ultimately will become non-vascular, and here remain as spores when the early outbreaks have been overcome, the microbes elsewhere being destroyed or their spores eliminated during the changes of growth and development. Then when the forces of the organism are exhausted by the evolution of puberty or other causes, the spores resting in the cornea or labyrinth will develop into foci and cause the infiltrations which determine the characteristic lesions. The retention, too, of spores in the testicles or ovaries seems to render transmission to the third generation at any rate credible.

This toxine theory of syphilis has been in my mind ever since I first formulated it in THE LANCET of Sept. 10th, 1892, and with increased experience I am the more impressed with its efficiency in explaining the phenomena of the disease.

Hertford-street, W.

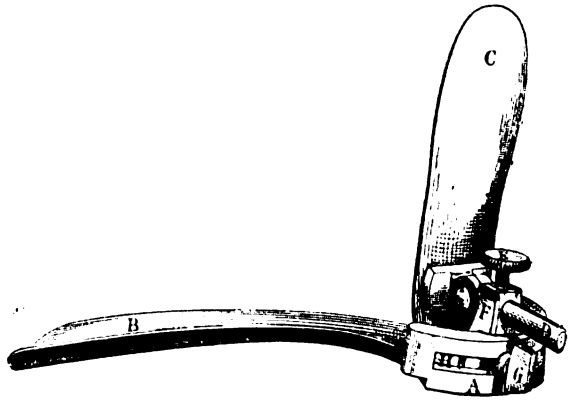
A NEW INSTRUMENT FOR TREATING DEFORMITIES OF THE HUMAN FOOT.

By R. MARTIN GIL, M.D.,

SURGEON TO THE HOSPITAL "NOBLE" OF MALAGA; CORRESPONDING MEMBER OF THE ROYAL ACADEMIES OF MEDICINE OF MADRID AND BARCELONA, ETC.

IF deformities of the foot were as common as they are generally strange and abnormal they would most assuredly for a very long time past have constituted a specialty by themselves, to the study of which many eminent men of science would have devoted their time and talent for the benefit of fellow-beings so frequently helpless and worthy of the deepest commiseration. In the course of the last few years a number of orthopædic societies have been founded in Europe and America. In England there are in certain hospitals departments for the treatment of this specialty; in France and Germany many distinguished medical men give their attention to cases of deformity of the foot and leg; the modern publications on operative surgery now treat of these affections at greater length, and of late years special treatises have been issued on the subject, among others the recent ones of Mr. Walsham and Mr. Kent Hughes. Both in these works and in some other pamphlets are to be found descriptions of a great number of instruments for keeping the foot straight and in a proper position, but in my opinion the majority leave something to be desired, for although many of them are excellent in their way they are still more or less defective. When the surgeon does not consider that the case calls for an operation and decides instead on employing one of these instruments, it at once becomes apparent that his skill and solicitude, owing to the imperfections of the invention, fall far short of coping with the difficulties of the case. The manufacturer of orthopædic instruments is then given an order for one, and when finished the inconvenience resulting from the complicated and bewildering combination of springs, screws, joints, hinges, and above all the straps and buckles, becomes painfully evident even if we omit to take into account the certainty of atrophy of the muscles supervening from its prolonged use. To avoid these drawbacks the surgeon employs massage, bandages, plaster-of-Paris, silicate of potash, gum, &c., which, even if they do not meet all the wants of the case, are at least not open to the reproach of being dangerous as are the majority of mechanical contrivances.

The number of cases of deformed feet which I have met with in my professional career are numerous. In those not operated upon by me—which has generally happened through opposition on the part of the family of the patient—the results have been far from encouraging. In many of them the evil continued as before, while aggravated by the check to the development of the limbs caused by the pressure of the apparatus. Quite recently, on the occasion of an operation on a little girl suffering from equino varus in both feet, I felt the want of an apparatus to keep the foot steady and straight after performing tenotomy. The deformity of the bones of the ankle-joint and the slackness of the sinews and ligaments of the outside of the foot rendered it difficult to retain this latter straight and in a proper position and to keep the bandages from moving. Failing to find among the contrivances known to me any to suit my purpose, I was obliged to invent that represented below. This apparatus consists of a circular plate of strong steel, A, with a radius of seven centimetres. A splint, B, is joined to the centre by



two screws, and is applied to the leg with a bandage. When the foot is placed upon the brass plate, C, it is kept steady with another bandage, and by means of the stem, D, which is joined to the plate, the toe being moved to the right or left as desired, leaving the foot in a fixed position by means of the screw, E. The piece, F, is then directed as required, the foot being placed in a normal position and kept in place by the use of the screw, G, which passes through the opening, H, and may be placed wherever its presence becomes necessary. The ring-catch, I, serves to keep the foot in a more or less vertical position as required. These positions are soon changed when, after the wounds inflicted in the operation are healed, massage of the joint has to be employed; it will then be sufficient to slacken the screws, E, G, and that of the ring-catch, I, so that both hands of the operator may be able to move the foot freely without removing the bandages. After the massage any person, however ignorant of mechanical contrivances, can easily place the foot in its former position by means of the screws already mentioned. This apparatus serves for all classes of patients, from children to adults. It is only necessary to exchange the splint, B, and the plate, C, which are held in place by two screws, for others of the measures needed. With children who have already been operated upon after walking and who are permitted to walk with, for example, the boots of Stillman on, these latter will

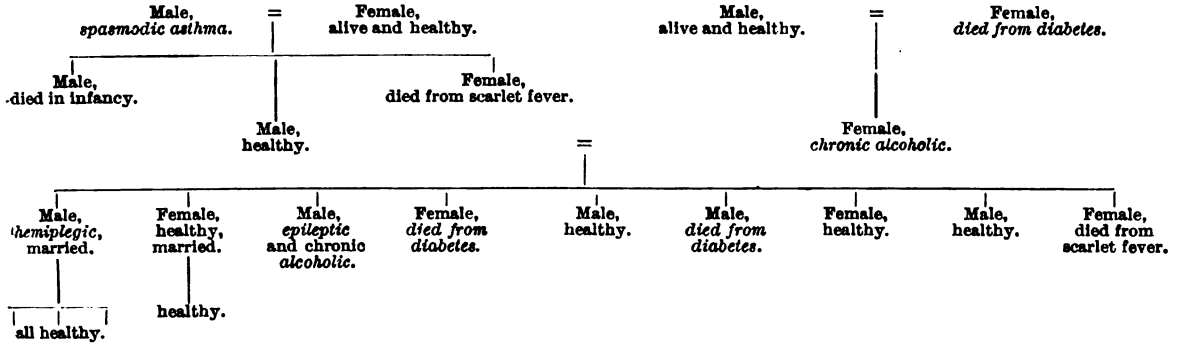
Digitized by Google

be replaced when they retire to rest by this apparatus, so that the foot may be constantly kept in the position desired without moving during sleep. It is likewise very applicable in other deformities, such as talipes varus, equinus, valgus, and calcaneus, flat-foot, &c., whether dating from birth or acquired after birth, when in connexion with it a plate of the form needed by each individual case is used. When it is a question of children who have not yet walked my apparatus is also useful, but I have kept more in mind those who have already walked for the reason that they are the most difficult to cure, and this is because with my contrivance they cannot place the foot on the ground, while with others known to me when patients are allowed to walk if they let the weight of the body fall on the point operated upon they may possibly do so in a manner liable to cause them injury. When my apparatus is employed the foot of the patient will be always held in a desirable position, and if the operation be not crowned with complete success the blame cannot be attributed to any defect in the position of the deformed member.

DIABETES AND NEUROTIC INHERITANCE.

By J. C. M. GIVEN, M.D. Lond.,
ASSISTANT PHYSICIAN TO THE LIVERPOOL SKIN AND CANCER HOSPITAL.

THE following pedigree, which I obtained when attending one of the cases of diabetes set out, is interesting as an example of how diabetes mellitus may be inherited and also of the fact now generally acknowledged that it may alternate with various neuroses. In this family of four generations (the fourth generation being only infants) there are three cases of diabetes mellitus, one of spasmodic asthma, two of chronic alcoholism, one of epilepsy, and one of hemiplegia the exact nature of which I could not ascertain.



Mossley Hill, Liverpool.

SOME EXCEPTIONAL CASES OF MALIGNANT DISEASE.

By HERBERT SNOW, M.D. Lond.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON.

CASE 1. *Simultaneous development of carcinoma in both parotid glands; excision; subsequent ovariotomy for cyst with twisted pedicle; recovery.*—On Aug. 9th, 1895, a swarthy young woman aged thirty-four years, married, with a child aged sixteen months, was admitted to hospital with symmetrical tumours below each ear. That on the left was as large as a hen's, and that on the right as a pigeon's, egg, and not dissimilar in shape. They were of eighteen months' duration, had commenced therefore during pregnancy, and nearly at the same time, without any other obvious cause. There was no family history of cancer and no symptom in the least indicative thereof. The only complaint was earache. The general health was fairly good and there was a total absence of emaciation or of pain about the new growths, which felt smooth and exactly like an ordinary lymphoma, though slightly more elastic. At the lower extremity of the left was a round lump thought to be a distinct gland, but which subsequently proved to be a lobular projection from the primary tumour. Both were increasing quickly in bulk and caused considerable disfigurement. Upon incision they showed to the naked eye the greyish granular base commonly indicative of malignancy; they were firmly embedded in the parotid tissue and were dissected out with difficulty. The facial nerve passed directly through the left, and its division could not be avoided. Under the microscope the appearances were pronounced by Mr. Plimmer, pathologist to the hospital, to be typical of malignant lymph-gland disease (lympho-carcinoma)—a view in which I concurred. With a few minute cysts containing a milky fluid were large masses of small lymphoid cells, proliferating exuberantly and eroding the surrounding tissues. Presumably, therefore, the disease originated in one of the parotid lymph-glands. While in bed it was discovered almost accidentally that there was also an abdominal tumour which had so far given rise to no symptoms. It was as large as a child's head and was extremely mobile, feeling like a tense cyst. It had been noticed for six or seven months. The patient was discharged for domestic reasons on Nov. 7 at her own request. She sought readmission, however, on Nov. 21st, with severe abdominal pain and tenderness, the temperature rising to 103·6° F. Two days subsequently laparotomy was performed and a cyst of the left ovary with a long twisted pedicle was removed. Apparently the torsion was of some weeks' duration, though no symptoms had arisen previously to the first discharge from hospital. The cyst-wall was anteriorly adherent to the parietes and was there gangrenous, with blackish contents; the parietes were infiltrated and almost gristly. A favourable recovery ensued. The patient was seen well on Feb. 4th, 1896, with no indication of recurrence in the parotids or elsewhere.

CASE 2. *Simultaneous development of carcinoma in the uterus and mamma.*—A woman aged sixty-two years, a widow, was admitted to hospital on Jan. 8th, 1896. A prominent livid boss of encephaloid carcinoma, soft and freely movable, was visible at the upper and outer part of the left breast. Its duration was three months, it was of rapid growth and subsequent to a blow. The axillary glands were slightly enlarged. There was no family history of cancer. The patient was worn and emaciated. She was admitted for operation. A complaint of vaginal discharge led to digital examination, and it was then found that there was also malignant disease of the uterine cervix, that organ being firmly fixed in the pelvis; there was a deeply excavated ulcer, with fetid discharge, and infiltration of the surrounding tissues. So far as could be ascertained it had commenced simultaneously with the breast-lesion. The woman remains (Feb. 6th) an in-patient in an incurable ward, the idea of operative interference having been abandoned.

CASE 3. *Malignant disease of both ovaries; excision; recovery.*—A woman aged thirty-two years, single, was admitted to hospital on Aug. 13th, 1895. A large fluctuating tumour, noticed for two months, distended the abdomen. The menses were regular. There were emaciation and shooting pain on the left side. The mother had her breast excised two years previously for cancer; the mother's mother had "cancerated" (*sic*) tumour of the small bowel. Until a month previously the patient had been a laundress, a calling

Digitized by Google

which furnishes a specially large number of malignant cases. Laparotomy revealed a large, irregularly bossy tumour of each ovary, that on the right being the larger. Both were mainly cystic, but had a considerable solid basis, which under the microscope proved to consist of spindle-celled tissue, with abundant roundish cells containing large multiple nuclei. They were therefore sarcomata of very virulent type. The patient was discharged well on Sept. 18th. She was subsequently seen as an out-patient in good health on Feb. 3rd, 1896.

Remarks.—The two cases first reported are in my experience unique. I had never previously met with what appears to have been an independent and nearly simultaneous development of malignant disease in distinct and more or less distant organs; though I am aware that rapid diffusion *per* the bone marrow has caused some cases of acute periosteal sarcoma to be thus described in Germany. In order to establish the possibility of so rare an event one must first negative all possibility of metastatic transmission, such as can nearly always be traced when the opposite mamma becomes carcinomatous. The clinical history of the preceding seems to me quite incompatible with the idea of secondary infection. The first case, moreover, presents additional interest in view of the pathological correlation, occasionally noticed, between the parotid gland and the sexual organs.

NORTH-WEST LONDON HOSPITAL.

A CASE OF ADDISON'S DISEASE; NECROPSY.

(Under the care of Dr. KNOWSLEY SIBLEY.)

IN almost every detail this case is a typical one of Addison's disease, and the condition was fully recognised long before the vomiting and rapidly increasing asthenia made it evident that a fatal termination would soon ensue. The duration of life in these cases is very uncertain; we have published in these columns the accounts of cases in which the first symptoms were those of sudden and occasionally fatal syncope, where pigmentation of the surface of the body had not been previously observed, and it was not known that the patient was affected with this, as yet, incurable disease. It is hardly possible in any case to ascertain the exact date of the commencement of the disease, and it is probable that the process of degeneration of the suprarenal bodies is always far advanced before the clinical signs of the affection reveal themselves. The examination of the suprarenals after death in Dr. Sibley's patient shows how complete the destruction of those bodies may be, so extensive that no suprarenal tissue can be found. It is, however, not possible to say how long a patient can live after complete destruction of these glands. For the notes of the case we are indebted to Dr. Robert R. Leatham, resident medical officer.

The patient, a well-developed but nearly mulatto-coloured girl twenty years of age, was admitted to the hospital on Jan. 28th, 1894. In her family history there was nothing of importance. Both parents were alive and well, the father being of Scotch and the mother of English descent. Tubercle and syphilis were absent, nor had any relative had an unusually dark skin. All her life the patient had enjoyed excellent health with the exception of some hip-joint trouble when three years of age, the result of a fall, and of recurring attacks of dyspepsia during the last two or three years. Four months previously to admission the present illness began. She observed, as did her friends, an alteration in the colour of the skin of the face and neck, the skin becoming gradually darker. The hands, arms, and nails soon became affected in the same way, and finally the skin of the entire body was pigmented. About a month afterwards, in the beginning of November, she began to suffer from palpitation, and in a few weeks sickness and vomiting with occasional attacks of faintness and cardiac pain commenced. These symptoms had continued ever since. Amenorrhœa had existed since September, the hair had been falling out, and there had been a steady loss of strength. She had not, however, been losing flesh. On her admission to the hospital she was found to be a well-nourished girl, with a skin uniformly darker in colour than normal and in tint closely resembling that of a mulatto. The deepest staining existed in the axilla, neck, and buttocks, the parts being of a rich deep brown, the face, thorax and abdomen being of a lighter colour. The areolæ were extremely dark, resembling those of pregnancy; and down the back, over the spinous processes, stretched a band of deep staining. Round the body in a line corresponding to the pressure of the waist-band and above the knees in the position pressed on by the garters passed bands of deeper tint, whilst the flexures of the knees and elbows also showed more intense pigmentation. The scalp was of a yellowish-brown colour, and a scar in the neck, the result of an old suppurating gland, was deeply stained. The skin was soft and moist. The mucous membrane of the mouth was decidedly darker than usual, and on the sides of the tongue were several small patches of deep brown pigmentation. The conjunctivæ were white and clear. On examining the various organs no sign of disease could be detected. The lungs were resonant everywhere, with normal vesicular breathing; and the heart, liver, and spleen were apparently perfectly healthy. The pulse was regular, of low tension, 90 beats to the minute, and with soft arterial walls. The urine was acid, of specific gravity 1020, and contained no albumin, sugar, or indican. There was no œdema of the legs, the knee-jerks were normal, and the hip-joints freely movable; there were no scars. The retinæ and discs were healthy, and round each disc was a well-marked choroidal ring. The uterus and ovaries were healthy, and the pelvis presented nothing abnormal. On Feb. 1st the patient commenced to vomit, and for the next three days was sick every morning. Her pulse varied from 75 to 95 per minute and was of low tension, but otherwise she kept pretty well. Her bowels were inclined to be constipated. On the 5th she was very sick and vomited frequently all day. Her pulse was decidedly weaker, being only 77 beats to the minute. The bowels were open three times, this being due to a dose of cascara sagrada given the night before. She complained of no pain or uneasiness, only of the constant annoyance from the sickness. On the 6th she was no better and the vomiting was nearly incessant, even a sip of water exciting it. Her pulse was very weak and her condition grave in the extreme, the patient being greatly exhausted. On the 9th there was no change, the sickness being most distressing and the pulse nearly imperceptible. With difficulty it was made out to be beating about 130 to the minute. She lay in a state of exhaustion all day, vomiting being excited by the faintest movement, and during the night she died very suddenly. Her temperature was subnormal in hospital from the time of admission.

The *necropsy* showed a well-nourished girl so stiff from the severe cold that rigor mortis could not be distinguished. The skin was deeply pigmented, especially in the parts previously indicated. The lungs were healthy and the mediastinal glands were not enlarged. The heart was of small size and thin-walled, the valves were normal, and the liver and spleen healthy. The left kidney was misshapen, the hilum being puckered, otherwise it was healthy. The suprarenal capsules were very hard, cutting like scirrhus, but retained their shape. The distinction between cortex and medulla was not apparent. On section they appeared to be bluish-white with yellow patches. There was no trace of breaking down. The left was slightly adherent to the surrounding tissues. The solar plexus and semilunar ganglion were removed. To the naked eye they exhibited no sign of disease. The uterus and appendages were normal. A small gland removed from beneath the scar in the neck appeared to be healthy. There was no sign of tubercle anywhere.

Remarks by Dr. SIBLEY.—The suprarenals were chemically examined by Professor Schäfer and Dr. George Oliver, who found a complete absence of any suprarenal tissue, and no suprarenal extract could be obtained from the glands—that is, no physiological action could be produced from the extract obtained. Examination of sections under the microscope showed nothing but fibrous and caseous tissue in various stages of degeneration, with considerable small-celled infiltration in places. No tubercle bacilli could be found.

ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

A CASE OF PERFORATING ULCER OF THE STOMACH; LAPAROTOMY; RECOVERY.

(Under the care of Mr. F. PAGE.)

WE are pleased to be able to bring forward the account of another successful operation for perforation of a gastric ulcer. In most respects the history was a typical one of gastric ulceration, and the sudden onset of the symptoms which characterise perforation completed the evidence of the disease available without abdominal exploration. As usual, the perforation was found on the anterior wall, and it was reached and suturing performed, apparently without difficulty, through the median incision. Mr. Page lays great stress in his remarks on the importance of early suturing, and we fully agree with the importance of this. It is a point which we have frequently impressed on the readers of THE LANCET and is strongly supported by the eight cases which we published in the "Mirror" last year. Of these patients five recovered and three died. Of the former the ages varied from nineteen years to thirty-one years and the duration of symptoms of perforation before operation from four hours to thirteen and a half hours. In the three fatal cases the ages of the patients were twenty-one, thirty, and thirty-three years, and the symptoms of perforation had existed for nineteen, nineteen and a half, and fourteen hours respectively. In only one of the eight (a successful operation) was the ulcer on the posterior aspect of the stomach. The importance of a careful examination of the abdomen is shown by the accumulation of fluid which was found and required to be removed from Douglas's pouch during the progress of the operation, and for which a second incision was necessary. For the notes of this case we are indebted to Mr. W. H. Vickery, surgical registrar.

A woman aged twenty-eight years was admitted to the infirmary on March 17th, 1896, with the history that for a few years she had suffered from gastric symptoms and on one or two occasions had had hæmatemesis, the vomited material being of the usual "coffee-ground" nature. At 10 A.M. on the morning of admission she was suddenly seized with a sharp abdominal pain, she became rapidly collapsed, and she vomited some brown fluid. On admission she was collapsed and all her symptoms pointed to perforation of a gastric ulcer. She was pale, her extremities were cold, her pulse was rapid and soft, her expression anxious, and her abdomen tender. She was at once anæsthetised (4 P.M.) and the abdomen was opened by a median incision. There was free gas in the peritoneal cavity, as well as fluid contents from the stomach. On further examination a small, circular punched-out looking ulcer was found on the anterior surface of the stomach near the lesser curvature and at the cardiac end of the middle of the organ. It had contracted friable adhesions to the under surface of the liver, which were easily broken down. A row of sutures was passed through all the coats of the stomach uniting the edges of the ulcer. The ulcer was then covered in with surrounding stomach wall, which was sutured with a row of Lembert's sutures, only passing through the peritoneal and muscular coats. A third row was passed outside this for further security. The peritoneal cavity was very carefully and thoroughly washed out and a glass drainage-tube passed into Douglas's pouch. The parietal wound was sutured in the usual way. The patient stood the shock of the operation well, and was taken back to bed at 4.40 P.M. At 5.30 P.M. two ounces of fluid were drawn from the drainage-tube, and the tube was exhausted every hour until 8 A.M. on March 18th. Altogether twenty-eight ounces were removed. At midnight a nutrient enema was given and retained, and this was repeated every four hours. She dozed at intervals during the night, and her general condition was satisfactory. On the 18th—that is, the day following the operation—she was troubled a good deal with hiccough, but she did not vomit. At midday she had a teaspoonful of meat essence, and this was repeated every four hours. She perspired freely and at times was very restless, her temperature ranging between 98·4° and 100·4° F. In addition to the meat essence she took nearly a pint of beef-tea and six ounces of whisky in the twenty-four hours. At 10 A.M. on the 19th a soap-and-water enema was given and the bowels opened, after which she slept comfortably. The bowels were again moved during the day. She took a large quantity of nourishment. She continued to make satisfactory progress, and on the eighth day after the operation she was allowed an oyster every four hours; on the next day she was given milk puddings. On the 28th the dressings were removed, when the wound was found to be healed and the stitches were removed. On the following day she was put on the ordinary fish diet, and on April 19th she left the infirmary quite well.

Remarks by Mr. PAGE.—There is one point of considerable practical import in this case which I should like to mention. After the sutured stomach was returned the abdomen was very thoroughly washed out with hot sterilised water till the fluid returned quite unstained. A sponge on a handle was then passed into Douglas's space, when the pelvis was found to contain a quantity of fluid stained by contents of the stomach. To remove this a second incision was made into the abdomen and a glass tube introduced into Douglas's pouch. Through this the pelvis was thoroughly cleansed by irrigation. I consider the success of this case is due to the circumstance that the abdomen was opened so soon—namely, six hours—after perforation occurred. The patient owes her recovery mainly to Mr. Ouston—the surgeon who saw her very soon after perforation—who at once placed her in a position to have an operation brought to a successful termination. I have seen the patient to-day (May 12th); she has gained weight and is bright and cheerful, looking, as she says she is, quite well.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Hypertrophic Pulmonary Osteo-arthropathy.—Thyroid Body in Graves's Disease.—Osteitis Deformans.—Carcinoma of the Transverse Colon.—Annual Meeting.—Debate on Proposed Admission of Women as Members.

THE annual general meeting of this society was held on May 19th, the President, Mr. BUTLIN, being in the chair. The business of the ordinary meeting was first proceeded with.

Dr. THORBURN and Mr. WESTMACOTT demonstrated the post-mortem appearances of a case of Hypertrophic Pulmonary Osteo-arthropathy. This rare disease was described by Marie in 1890, and in the *British Medical Journal* of June 3rd, 1893, Dr. Thorburn recorded three examples. Of these cases one, a lad, remained under observation until his death, his clinical symptoms undergoing no material alteration. The post-mortem examination was very complete and showed almost universal erosions and articular changes. The lungs, spine, right suprarenal capsule, and right tibia presented tuberculous lesions and there was extensive amyloid disease. The skull was much thickened, roughened internally, sclerosed, and devoid of diploe; in his facial bones, ribs, sternum, vertebræ (except in the carious region), and clavicles no changes were observed. The limb bones were covered with a rough, porous layer of sub-periosteal bone. Their compact tissue was sclerosed and their medullary cavities encroached upon by new bone. These osseous deposits were especially marked in the shafts of the bones and in the attachments of muscles and fasciæ. The shoulder-joints contained an excess of clear fluid, and the cartilages of the heads of the humeri were eroded, especially at their margins; the synovial membranes were normal. In the hip-joints closely analogous appearances were observed, and the hips and shoulders were all remarkably symmetrical in the extent and distribution of the cartilaginous erosions. The elbow and knee-joints also formed a symmetrical group containing less fluid than the hip and shoulders, but with similar cartilaginous erosions, and with thickening of the synovial membranes. In the wrists, ankles, radio-ulnar, carpal, tarsal, and other small joints erosions of cartilage, principally marginal, were also found. The general condition was thus a highly symmetrical and almost universal osteo-periostitis of the limb bones, with atrophic erosion of the cartilages of their joints; the viscera indicated a somewhat extensive but much subdued tuberculosis. Mr. Thorburn regarded as unsatisfactory the theory of Marie, which attributed the disease to the absorption of ptomaines from suppurating foci, and found no evidence in favour of Bamberger's view that it was due to venous congestion. While reserving any strong expression of opinion he was inclined to

Digitized by Google

endorse his own suggestion based on the clinical appearances, that "hypertrophic pulmonary osteo-arthropathy" was the result of a diffused but very mild tuberculosis of bone.—Mr. GODLEE said that the confusion in the literature of this subject was in part due to the way in which it had been introduced to the profession by Marie, who dwelt chiefly on the difference between this osteo-arthropathy and acromegaly. The specimens shown were of great rarity, and they appeared to correspond very closely with the description of Bamberger. Mr. Godlee referred to two cases which had been under his care. The first was that of a man who suffered for the whole of his life from cough. His fingers had been clubbed as long as he could remember and his expectoration had been offensive for three years. He had developed lately an appearance of the wrists and ankles like that of the photographs which had been shown. There was no very distinct enlargement of the shafts of the bones, but there was effusion into the joints, with pain, limitation of movement, and some fever. There was no reason to believe that the patient was tuberculous. The second case was that of a man who had suffered from pleurisy and bronchiectasis since 1891; there was clubbing of the fingers, with swelling of the wrists and ankles and effusion into the knee-joints. He had described a case in 1885 as one of "clubbing of the ankles and wrists" which occurred in a case of old empyema. If a reclassification of these cases were carried out a considerable number of them would fall into the group of septic osteo-arthritis, a group quite distinct from rheumatism. In the first of the cases he had referred to he had obtained skiagraphs of the limbs, and the pictures did not demonstrate enlargement of the bones.—Mr. THORBURN, in reply, held that the cases Mr. Godlee had related belonged to an entirely different group. The enlargements which occurred in congestive diseases were likewise quite distinct from those he described and exhibited.

Mr. EDMUNDS placed on record some further observations and experiments on the Pathology of Graves's Disease. The removal of the whole of the thyroid gland proper and also of one parathyroid gland was not a fatal operation in dogs, a single parathyroid gland being sufficient to prevent death or any symptom of athyroidea. If, however, both parathyroid glands were removed it was necessary to leave a considerable portion of the thyroid gland proper, in order that the dog might live; if even as much as 40 per cent. of the thyroid gland were left chronic tremors and inability to stand might result. The changes in the parathyroid gland thus left were to the naked eye a certain amount of hypertrophy; under the microscope this appeared generally to be due to a simple increase in the number of secreting cells, together with some thickening of the connective tissue. Occasionally an area of very large cells might be found and sometimes columnar cells almost or quite constituting a tubule or small vesicle; occasionally a few minute collections of colloid secretion were seen, but the parathyroid did not develop into thyroid tissue proper even in six months. The same negative result occurred in rabbits. The portion of thyroid tissue proper left also hypertrophied, the vesicles enlarged and became oblong and branched, the lining membrane projected in ridges into the cavity of the vesicles, the secreting cells became columnar, and the colloid secretion became less, being in many vesicles replaced by a fluid which stained much less deeply. All these changes which occurred in a remnant of thyroid tissue proper were also to be found in the enlarged thyroid gland of Graves's disease; indeed, the resemblance was so close as to lead to the inference that the two conditions were of the same nature. With respect to exophthalmos the excision of the parathyroid glands in rabbits seemed to cause the opposite condition of enophthalmos. In dogs a pathological widening of the palpebral opening was occasionally observed after partial excisions of the thyroid gland. The experiments had been made at the Brown Institution.

Dr. FIELDER exhibited the skeleton of a well-marked case of Osteitis Deformans. The patient was a female aged forty-five who had been suffering from the disease since the year 1891. She had had twelve confinements and six of her children were dead, including two who died from tuberculosis. The husband showed old choroiditis due to syphilis. There had been great pain in the limbs, which was always present and was worse at night. The bowing of the legs progressed rapidly and the patient estimated that she had lost four inches in height. The breathing was diaphragmatic owing to the falling together of the ribs, and most of the bones were affected, except those of the feet and the radius and ulna. The osseous changes were chiefly marked about the shoulders and knees, and were more advanced on the right side. Before death a tumour was discovered in the neighbourhood of the sacro-iliac joint, and this was afterwards found to be a mixed spindle and round-celled sarcoma. The greatest girth of the skull was twenty-four inches and at one place it was an inch and a quarter in thickness. The basal skull bones were unaffected and the vertebræ were extensively ankylosed together. No medicinal treatment succeeded in relieving the pain, but the patient seemed to do best on a mixture of iodide of iron and liquor sodii arseniatis.

Dr. NORMAN MOORE exhibited a specimen of Carcinoma of the Transverse Colon. The growth, which showed much thickening with ulceration of the mucous surface of the transverse colon, occupied its middle part. It was a spheroidal-celled carcinoma. The growth was adherent to the stomach, but had only penetrated to the sub-mucous coat of that organ. There was a large secondary growth somewhat higher up in the colon, but no other secondary growths. The patient was a man aged forty-five and his illness lasted seven months. The case was remarkable in the situation of the secondary growth and in the fact that, with the exception of slight diarrhœa without blood in the stools for four days, the symptoms were altogether gastric.

The following card specimens were shown:—

Dr. TYSON (Folkestone): Elongated Appendix with Calculus.

Dr. SELIGMANN: Streptothrix Maduræ.

Mr. JOHNSON SMITH: Filariæ from Lymph Scrotum.

Dr. ROLLESTON: (1) Mediastinal Growth from the Thymus; and (2) Large Cyst in Carcinoma Mammæ.

Dr. HAWKINS; (1) Perforation of Gall-bladder in Febris Enterica; and (2) Horseshoe Kidney.

Mr. S. G. SHATTOCK: Cultural Variation in Streptococcus Pyogenes Bovis consisting of Mossy Outgrowths from the Colonies in Stab Gelatin Cultures.

Dr. OGLE: (1) Congenital Atresia of Pulmonary Artery; and (2) Gumma or Aneurysm of the Heart.

Mr. MALCOLM: Sarcoma of the Kidney.

Mr. TARGETT: Adrenal Tumour of the Kidney.

The business of the annual general meeting was then proceeded with, and it attracted a very large muster of members in view of the fact that the question of the admission of lady members was to be discussed. The report of the council was read by the senior secretary. There were 708 ordinary members of the society. Death had carried off amongst others M. Louis Pasteur, Dr. J. S. Bristowe, and Sir J. Tomes. The fiftieth anniversary of the society would fall during the coming session, and the council proposed to celebrate this by a presidential review of the history of the society combined with a conversazione. The financial statement showed a small deficit, but it was explained that this was due to the fact that a large number of subscriptions still remained unpaid, and the belated members of the society are hereby invited to note this fact. The following were elected as honorary members of the society:—Professor Bouchard (Paris), Professor Koch (Berlin), Professor Welch (Baltimore), and Professor Ziegler (Tübingen).

Votes of thanks having been accorded to the retiring officers and members of council the PRESIDENT, in a few introductory remarks, explained that in February last a lady had applied for membership of the society. The application came before the council in March and was deferred to the April meeting, there being a difficulty in arriving at a conclusion as to a right interpretation of the by-laws, at the time of the making of which there was no probability of women applying to be admitted. The council thought it desirable that the matter should be threshed out at the annual meeting, and asked Mr. Stanley Boyd to move a resolution standing in his name to the following effect: "That, in the opinion of this meeting, it is expedient that ladies, who are duly qualified medical practitioners, should be eligible for the membership of this society."

Of the lively debate which followed we are only able to give the briefest outline.

Mr. BOYD said that he considered it would do good to the medical women, while it would do no harm to the society. He said that the difficulty found in alluding to certain subjects before women, though it hampered ordinary conversation and required a distinct effort in scientific conversation, was yet less difficult before a society of mixed sexes than in the case of a man lecturing to a class composed solely of women. The admission of women would not only be extending a friendly feeling towards them, but would stimulate

Digitized by Google

them to work. Their opportunities of obtaining material were too few and their numbers too small to justify them in forming a society of their own.

Mr. BERRY, in seconding the motion, appealed to the generosity of the members and asked them, by admitting lady members, to follow the example of the Anatomical Society and the Society of Anæsthetists.

Dr. HERRINGHAM considered the question to turn on the point whether it would inconvenience the majority of the members or not.

Dr. FLETCHER LITTLE besought the members to consider what the outside public would say to an adverse vote on this matter.

Mr. WALLIS and Dr. KANTHACK both confessed to a feeling of great diffidence when addressing mixed classes, and the former said that the British Nurses' Association could not be pointed to as an example of a happy family of mixed sexes.

Dr. HORROCKS felt that the admission of women would not hinder the attainment of truth.

Dr. NORMAN MOORE found himself forced to the conclusion that this was only another instance of the desire of ladies to push themselves forward into places where a large majority of medical men did not wish to have them.

Dr. HARE was impelled by his declared objection to the admission of women into the medical profession to *a fortiori* exclude them from the Pathological Society.

Dr. DICKINSON, recalling that the society had grown up into a flourishing manhood under certain rules, deprecated strongly a change which would entirely alter the tone of the meetings.

A vote being taken by show of hands, it was found that 23 members were in favour of the motion and 43 against it. The motion was accordingly declared to be lost.

The result of the ballot for the election of officers and council for the ensuing year was declared as follows:—President: Henry Trentham Butlin, D.C.L., F.R.C.S. Vice-Presidents: William Richard Gowers, M.D., Samuel West, M.D., Norman Moore, M.D., Seymour Sharkey, M.D., Arthur E. J. Barker, F.R.C.S., Frederic S. Eve, F.R.C.S., Samuel G. Shattock, F.R.C.S., and Frederick Treves, F.R.C.S. Treasurer: Sidney Coupland, M.D. Honorary Secretaries: J. H. Targett, M.S., and Richard G. Hebb, M.D. Council: Wilmot Parker Herringham, M.B., A. A. Kanthack, M.B., Hector Mackenzie, M.D., Julius Dreschfeld, M.D., G. Newton Pitt, M.D., H. D. Rolleston, M.D., Charles Scott Sherrington, M.B., F. Charlewood Turner, M.D., A. F. Voelcker, M.D., Hubert Montague Murray, M.D., Gilbert Barling, M.B., James Berry, M.B., W. G. Spencer, F.R.C.S., Anthony Bowlby, F.R.C.S., E. Hurry Fenwick, F.R.C.S., H. Betham Robinson, F.R.C.S., Stephen Paget, F.R.C.S., Bilton Pollard, M.B., Raymond Johnson, F.R.C.S., and C. E. Leopold B. Hudson, F.R.C.S.

OPHTHALMOLOGICAL SOCIETY.

Restoration to Normal Vision after Sympathetic Ophthalmitis.—Extraction of a Dislocated Lens with good Result.—Hereditary Optic Nerve Disease in a Mother and Three Children.—Spurious Optic Neuritis.—Lymphangiectasis of the Eyelids.—One-sided Paralysis of the Sixth Nerve associated with Contraction of the Orbicularis and Retraction of the Globe on Inward Rotation.—Transplantation of Skin to the Surface of the Eyeball for the Cure of Symblepharon.—Posterior Lental Opacity, with remains of Hyaloid Artery and Coloboma Lentis.—Detachment of the Retina treated by Drainage.—Case of Proptosis, Optic Atrophy, and Ophthalmoplegia.

A CLINICAL meeting of this society was held on May 7th, Mr. E. NETTLESHIP, F.R.C.S., being in the chair.

Mr. ANDERSON CRITCHETT exhibited a case illustrating Restoration to Normal Vision after Sympathetic Ophthalmitis. An attempt was made to save an eye which had been injured by a nail; the cornea and lens had been wounded. The attempt failed, and the eye was excised thirty-five days after the accident. Twelve days after the excision of the injured eye the other eye became inflamed and vision was reduced to < fingers. Under the use of atropine and mercurial inunction the inflammation subsided gradually and the vision was eventually restored to normal.—Mr. CRITCHETT also exhibited a case of Extraction of a Dislocated Lens with a good result. The patient was a middle-aged woman. Two months before her visit to the hospital she received a blow on the right eye by which the lens was displaced downwards. The left eye had been injured twenty-three years before; at that time there had been also an attack of inflammation in the right eye. The dislocated lens was removed with a vectis; there was no loss of vitreous and vision was eventually $\frac{6}{60}$. The section was within the cornea. The vectis was preferable to the spoon in some cases, as it sank into the lens and held it more securely.—The PRESIDENT expressed the opinion that the second case was another instance of recovery from sympathetic ophthalmia, which added to the interest of the operation that had been performed. The case also raised the question as to whether the removal of the injured eye affected the condition of the other.

Dr. R. D. BATTEN showed instances of Hereditary Optic Nerve Disease in a mother and three children. The mother's sight had failed when she was twelve years old; one of her sisters, aged thirty-three, had the same affection, also one brother. In the mother's case the vision was reduced to $\frac{1}{60}$; the optic discs were atrophic, and there was slight contraction of the visual field. In the younger generation one boy and two girls were affected; their sight had failed at about twelve years, the same age as the failure in the mother's case. In the boy vision was $\frac{6}{18}$ and there was a central scotoma. In the eldest girl there were pallor of the discs, several scotomata, and colour-blindness. In the other girl the signs were less marked. There was no other disease in the family.—Dr. HABERSHON said there was no doubt that this was the same disease as Leber described. The sight usually failed at puberty or the menopause, rarely as young as five or eight years.

Mr. HOLMES SPICER showed a case of Spurious Optic Neuritis. The patient was a boy aged eleven and a half years, whose refraction in each eye was emmetropic and whose vision was $\frac{6}{9}$. His visual fields were normal; his light and colour sense were normal. Both optic discs presented the appearance of the early subsidence stage of severe optic neuritis; their edges were quite indistinct; they were very pale; the vessels were covered in places with a light veil of haze; and there was swelling amounting to about 3 D. The patient had been under continuous observation for three years, and there had not been the slightest change in the appearance of the optic discs.—Mr. HARTRIDGE disapproved of the term "spurious"; he should regard the case as one of persistent optic neuritis in which the macular fibres had escaped.—Dr. R. D. BATTEN was reminded of those cases in which an appearance of neuritis confined to one side was caused by tilting of the optic disc.—Mr. MARCUS GUNN inquired if any case had been recorded in which recovery had taken place after optic neuritis; he had once observed this in an adult.—Mr. SILCOCK mentioned a case exhibiting similar appearances in the fundi; the patient was thought to have cerebral tumour; the appearances were unchanged though they had been closely observed for a long time.—Mr. ADAMS FROST did not consider the long persistence of this condition without change necessarily excluded the presence of optic neuritis.—Mr. HOLMES SPICER, in reply, said he regarded the condition in this case as a physiological one simulating optic neuritis; if it were inflammatory it would be necessary to assume that serious inflammation could last for years without producing any impairment of function in such a delicate structure as the optic nerve.

Dr. D. MOWAT showed a case of Lymphangiectasis of the Eyelids. A small, soft, ill-defined swelling had first appeared in the lower lid; it increased slowly for some months, then spread to the upper lid. The swelling could be displaced from one lid to the other by pressure; if pressure was made on both lids the swelling appeared behind the ear of the same side; there were communicating channels over the zygoma. The swelling had steadily increased so that it was no longer possible to transfer the fluid from one part to another.

Dr. MACLEHOSE exhibited a case of One-sided Paralysis of the Sixth Nerve associated with Contraction of the Orbicularis and Retraction of the Globe on Inward Rotation. It belonged to a definite group of cases, of which he had seen several which all presented the above signs with some variations. Although he called it paralysis of the sixth nerve, he thought the condition was congenital and depended on variations in nerve-supply or muscular development.

Dr. BELL TAYLOR showed a case in which Transplantation of Skin to the Surface of the Eyeball had been effected for the Cure of Symblepharon. The patient, a male aged forty, had symblepharon following a burn by hot slag. The lower lid was firmly adherent to the globe, covering the lower third of the cornea. Repeated attempts to secure separation of

Digitized by Google

the adherent tissues by the usual methods failed. Eventually the lid was dissected off the eyeball, and a piece of skin from the upper eyelid of the uninjured eye was transplanted on the surface of the globe, to which it readily became united.

Mr. CARTWRIGHT exhibited a case of Posterior Lental Opacity, with the remains of the Hyaloid Artery and Coloboma Lentis. There existed a double notch in the lens, directed upwards and outwards, through which the suspensory ligament could be seen attached to the remains of the fibro-vascular sheath. The remains of the hyaloid artery appeared to be floating free in the vitreous.

Mr. F. S. EVE showed a case of Detachment of the Retina successfully treated by drainage. The patient, a young man, showed evidence of choroiditis and vitreous opacities before Christmas, 1895; in February the retina became suddenly detached. Treatment by iodide of potassium, pilocarpin, and the recumbent position had no effect. An incision into the sclera was made, a trocar and cannula were inserted, the fluid withdrawn, and a horsehair drain placed in the eye. Seven weeks after no detachment could be made out and the visual field was normal.

Mr. MARCUS GUNN exhibited a case of Proptosis, Optic Atrophy, and Ophthalmoplegia. A female aged sixty-seven suddenly had proptosis of the right eye. The third, fourth, and sixth nerves were paralysed, the optic nerve was atrophied, the pupil was dilated and inactive, and the conjunctiva œdematous. He thought the case was probably one of hæmorrhage from an aneurysm of the ophthalmic artery.—Mr. EVE had had a case with a similar history, which proved to be a pulsating sarcoma of the back of the orbit.

EPIDEMIOLOGICAL SOCIETY.

Infectious Sore-throats and Diphtheria.

A MEETING of this society was held on May 15th, Mr. SHIRLEY F. MURPHY, President, being in the chair.

Dr. GEORGE REID read a paper on Infectious Sore-throats and Diphtheria, in which he quoted Dr. Thorne Thorne's theory, propounded in the Milroy Lectures, that "attacks of so-called sore-throat exhibited under favouring conditions a progressive development of the property of infectiveness, culminating in a definite specific type indistinguishable from diphtheria." He then referred to the so-called pseudo-diphtheria, bacteriologically different from, though clinically identical with, diphtheria proper, and observed that there were probably several distinct diseases comprehended under the designation of follicular tonsillitis, also of a microbic nature, common quinsy being a simple catarrhal affection and scarlet fever and mumps not being properly included among throat diseases. He next described an outbreak originating in an infants' school, where an obstructed drain had been opened, and extending later to the other departments until fully a third of the 300 children had been attacked as well as the whole of the teaching staff and the master's family. Many were seriously ill and in all the swelling of the glands was very conspicuous, but in none was there any membrane or rash. The acute symptoms usually subsided after the fourth day, though the swelling persisted longer, but no case ended fatally. There could be little doubt as to the outbreak having been originally caused by the foul effluvia from the drain; but though the water-closets, urinals, and sink-wastes of the schools and house were all in direct connexion with the drain the extension of the disease beyond the infants' department occurring a week or ten days later was probably due to personal intercourse, yet there were but few cases in the village among children not actually attending school. He next referred to the account given by Dr. Wheaton in a paper read before the society two years ago of an outbreak in South London in 1890, when 150 or more children were attacked with similar symptoms and equally non-fatal results ensued, though these cases presented a transient filmy exudation, but without any paralytic sequelæ; and to a like epidemic in 1893 in a town with 10,000 inhabitants, in which also no diphtheritic bacilli were detected, as well as to other outbreaks described by Dr. Thresh and one observed by Dr. Kenwood at Finchley last year which was unmistakably connected with the supply of milk from a dairy where some of the cows were suffering from a febrile affection and had eruptions on the udders.

Dr. WILLOUGHBY said that the membrane is not an essential phenomenon of diphtheria, and they ought rather to speak of Löffler's, streptococcal, and staphylococcal diphtheria. The three microbes might be present singly or variously associated, Löffler's being the cause of the albuminuria and paralytic phenomena, the streptococci of the purulent, and the staphylococci of the fibrinous, exudations. All three bacteria, including Löffler's, have an extra-corporeal existence which explains the *de novo* origin of both true and false diphtherias.

The PRESIDENT remarked that progressive development was seen in cholera, persons arriving from an infected locality having the Koch's bacillus in their intestines though perhaps showing no signs of the disease.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Cancer of the Rectum.—Tubal Pregnancy.—Hæmatemesis and Melæna.—Exhibition of Cases.

A MEETING of this society was held on April 17th, the President, Mr. MAYO ROBSON, being in the chair.

Mr. LITTLEWOOD read the notes of eight cases of Cancer of the Rectum on which he had successfully operated during the past eighteen months. In all the cases he avoided making a preliminary colotomy, and he advocated this plan whenever the intestinal tract about the disease could be thoroughly emptied. The operations were all performed in the prone position, as recommended by Mr. Godlee, and the great advantages of this position were discussed. In three of the cases the growth was near the anus, and after removal the divided portion of the bowel was attached to the surface by deep sutures and drained posteriorly. In five cases the disease was high up, so that part of the sacrum was divided to facilitate removal. In four of these the divided ends of the bowel were united, a Murphy's button being used for this purpose in one case, but without a good result, and a Robson's bobbin for the other three; in one of these latter there was good union, all the motions passing the natural way, but in the other two a fistulous opening in the posterior part of the bowel was formed. These last-mentioned operations have, however, only been done six and four weeks ago respectively and there is every reason to think that the fistulous openings will become closed. Some of the patients suffered from temporary mania after the operation.—The PRESIDENT considered that the chief points in favour of this operation were the great facility in exposing the rectum, the use of the bougie in showing the limits of the bowel, and the stitching together of the ends of the intestine. He thought very highly of this method of operating.—Mr. W. H. BROWN preferred to have colotomy performed a few weeks beforehand.—Mr. WARD agreed with Mr. Brown, particularly in those cases where the growth affected the rectum and anus.—Mr. WOODCOCK spoke of the dementia following severe operations and mentioned four cases which had occurred in his experience.—Mr. LATOUCHE mentioned that one of Mr. Littlewood's patients whom he was attending already suffered from secondary deposits in the liver.—Dr. SOLLY thought that the dementia might be produced by fæcal poisoning.

Mr. E. O. CROFT read a paper giving the clinical history of three cases of Tubal Pregnancy. Case 1.—This patient was a multipara, thirty-seven years of age, who had for six weeks suffered from amenorrhœa and shown symptoms of pregnancy, followed by irregular hæmorrhage and pain for nine weeks. The decidua came away shortly after the bleeding commenced. The uterus was enlarged and displaced forwards by effusion behind the cervix. Abdominal section was advised, but operation was refused. The swelling subsequently increased, after which there was escape of tarry blood from the rectum, followed by septicæmia, acute peritonitis, and death. The necropsy showed an extra-peritoneal hæmatoma, a rupture of the tube downwards into the broad ligament, an opening into the rectum, and a small recent opening above into the peritoneum. Case 2.—This patient was twenty-seven years of age and had one child who was two years old. There was no history of pregnancy, neither were there any symptoms of it, but there had been irregular bleeding and spasmodic pains for twelve months. A tumour could be felt above the pubes, and there was also a soft swelling behind the cervix. On abdominal section tarry blood was found in the peritoneum, partially limited by false membrane above. The left Fallopian tube was enlarged, measuring three and a

Digitized by Google

half inches by one inch, and it was removed together with the ovary. It contained a tubal mole with the remains of the amniotic cavity and chorionic villi; the ostium was closed. The right tube and ovary were congested, but not distended; the ostium was patent. The patient recovered. Case 3.—This patient was a multipara and thirty-three years of age. Eight weeks after pregnancy was suspected there were irregular hæmorrhage and labour-like pains, continuing for three months. An oval tumour could be felt above the pubes on the right side. On abdominal section the tumour was found to be about the size of a lemon and consisted of the right Fallopian tube enlarged and embedded in dense adhesions. It was removed together with the adherent ovary, and was then seen to be unruptured and to be filled with a mole showing chorionic villi and an amniotic cavity; the ostium was closed.

Mr. SALISBURY read a paper on a case of Severe Hæmatemesis and Melæna. The patient was a sallow-complexioned woman forty-five years of age much addicted to tea-drinking and a sufferer from "chronic indigestion" unattended by gastrodynia. She ceased menstruating two years ago. On Feb. 28th she complained of a "sinking feeling" in the abdomen, and in the evening she became extremely collapsed, vomited two or three pints of venous-looking blood and passed two or three pints of very offensive tar-like motions. Ergotine was given subcutaneously and ice to suck; nutrient suppositories and enemata were also used. On March 2nd while straining at defecation she again vomited blood and on March 6th she became delirious. On March 7th she again passed copious tar-like and very offensive motions. She was now delirious and completely blanched; the pulse was not perceptible at the wrist and the heart sounds were scarcely audible. Injections of ergotine were given repeatedly and a pint of normal saline solution (one drachm to one pint) was injected into the vein at the bend of the elbow, after which there was a slight improvement. For the next few days the patient hovered between life and death, but by March 10th she was improving slowly; on March 30th she was able to get up, and a fortnight later she came downstairs daily.

Mr. H. SECKER WALKER showed two cases of Suppurative Disease of the Middle Ear and Mastoid Cells in which Stacke's operation had been performed. In one case the mastoid cells were so much diseased that a large cavity had been left in the bone and this had since been "papered" with epithelium, giving a good result with improved hearing and cessation of discharge. In the other case facial paralysis had occurred a week before operation and this had since quite passed off.—Mr. SECKER WALKER also showed a Suction Curette for soft cataract; it was made of glass so that it could be sterilised by boiling.

Dr. CHURTON showed a male patient aged eighteen years who was admitted into the Leeds Infirmary on Feb. 22nd with General Chorea. In 1894 he had rheumatic joints and for four days was unable to work. Slight chorea followed, but he continued to work and after some weeks recovered. In October, 1895, after kneeling in wet sand he had pain in both knees; his hands afterwards became painful and swollen, but he kept at work, and towards the end of January, 1896, he had apparently almost recovered. On Feb. 5th he had a violent quarrel with a relative, on Feb. 6th there were choreic movements in the right side of his face, his right arm and leg, and on Feb. 8th his right hand was swollen and painful. On Feb. 13th he was nearly well, but on this day a serious quarrel occurred with the foreman of his department, and on Feb. 14th the chorea returned in his right hand, quickly spreading to all his limbs. The case illustrated the general principle enunciated by Dr. Churton at a recent meeting of the society[1] and founded upon observations in thirty-three cases, that in a person about to be rheumatic the first point of attack is determined by local chill, injury, or shock. If in a young person the organ thus damaged be the brain chorea or some other cerebral disorder will be the first and sometimes the only result.

Mr. WEST (Morley) and Mr. LITTLEWOOD showed a boy aged fifteen years who had been operated on for Acute Intestinal Obstruction on March 9th, 1896. The obstruction was in the small intestine and was caused by a coil which had become adherent in the pelvis to the side of the rectum and had invaginated a portion of the rectal wall; this could be felt before the operation. The adhesion was about the size of a half-crown and was separated; it bled freely, and at the edges there was some purulent lymph with a distinctly fæcal odour. The parts were carefully sponged and the abdomen was closed without drainage.

Mr. LITTLEWOOD showed a man aged thirty-seven years on whom he had operated for Diffuse Popliteal Aneurysm, removing about twelve ounces of blood-clot together with the aneurysmal portion of the artery. The patient made an uninterrupted recovery and now walks about without any difficulty.

[1] THE LANCET, Feb. 22nd, 1896, p. 487.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Recent Results of the Treatment of Diphtheria by Antitoxin.—Hemianæsthesia.

A MEETING of this society was held on May 5th, Dr. ADOLPH BRONNER, President, being in the chair.

Dr. H. J. CAMPBELL read a paper upon Recent Results of the Treatment of Diphtheria by Antitoxin. After giving a summary of the statistics of the treatment both at home and abroad Dr. Campbell discussed in some detail the recent report of the medical officers of the Metropolitan Asylums Board hospitals, and pointed out that these statistics were not open to the same objections as some of the foreign records, in that the cases were all subjected to the examination of the medical man sending the cases up and to the expert opinion of the medical officer, in addition to the bacteriological examination of the throat, so that the patients were all suffering from clinical and not from what might be described as bacteriological diphtheria. The question of dosage was then referred to, and on the authority of Dr. Goodall it was stated that in the Eastern Hospital larger doses of antitoxin had been used recently with better results than they had before obtained. The mode of action of the remedy was then considered and the experiments of Fischel and Wunschheim were quoted in support of the view that the antitoxin does not function as a bactericide, nor does it simply neutralise the toxine, but apparently acts upon the tissue cells in such a way as to enable them to destroy, or at least to render inert, the injurious action of the toxine. It was pointed out that in all diseases associated with the presence of toxines it was of the utmost importance to keep the kidneys well flushed, as the toxic bodies were eliminated by these organs. The results obtained in the prevention of diphtheria by using the antitoxin as an immunising agent were next described, and Ohlmacher's and Biggs' observations upon the length of time that the immunity persists were referred to. In conclusion, an account was given of the pathological effects produced by the remedy itself.—Dr. S. JOHNSTON, Dr. GOYDER, and Mr. MERCER made remarks.—The PRESIDENT discussed the complications met with in diphtheria, and pointed out that since the introduction of the serum treatment the onset of paralysis was not prevented and there were more cases of nephritis. The question of the possible advantages to be obtained from the local use of antitoxin was raised, and Dr. CAMPBELL replied.

Dr. MAJOR read notes of a case illustrating the clinical significance of Hemianæsthesia. A man aged fifty years had been ailing for three months. There had been headache, deafness on the right side, failure of sight, slight failure of power of the right arm and leg, some numbness in the legs, and loss of taste and smell. There was no history of "stroke." When the patient first came under observation there was very slight motor failure on the right side, but there was complete right hemianæsthesia of the skin and of the mucous membranes and also of the special senses. The optic discs were clear; the field of vision was markedly contracted, especially on the right side. Perimetric tracings were exhibited. The patient looked well; there was no obvious paralysis, and no mental defect. The right plantar reflex was reduced. The question of diagnosis, the exact seat of the lesion, and its probable nature were discussed. It was pointed out that in cases of hemiplegia from hæmorrhage or thrombosis motion is often alone affected, because the posterior part of the internal capsule had escaped injury, the lenticulo-striate artery being situated in the anterior part. If in these cases sensation be more or less affected it is reasoned that the lesion has to some extent involved the posterior extremity of the internal capsule. In the case under consideration there was little motor paralysis but complete anæsthesia of one side involving touch, pain,

Digitized by Google

and temperature—the skin, mucous membranes, and special senses being all implicated. The differential diagnosis was discussed and the views of Ferrier quoted as to the results of section of the posterior division of the internal capsule. With regard to the eye troubles in lesions of the internal capsule the views of Gowers, Ross, and Ferrier were mentioned, the latter being of opinion that besides hemianopsia cases were occasionally found of crossed amblyopia, as in the one under consideration.—The case was discussed by Mr. FARROW, Dr. H. BRONNER, and the PRESIDENT, and Dr. MAJOR replied.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

The Liver.

A MEETING of this society was held on May 6th, Dr. MUTCH, President, being in the chair.

Dr. W. B. RANSOM read a paper on the Liver. Attention was drawn to the remarkable power of regeneration of this organ. The functions of the liver in regard to fat, glycogen, and sugar were discussed and the conclusion drawn that the greater part of the liver glycogen is normally converted into sugar, not by a ferment, but by the hepatic cells. In regard to bile formation, the seat of blood destruction was considered and the view expressed that it normally commences all over the body and not exclusively in the spleen. Microphotographs were shown of the deposit of iron in the liver in pernicious anæmia. In the case of a man with biliary fistula the daily quantity of bile passed was found to average thirty ounces, the colour being always yellow. The stools remained inoffensive and the patient had a good appetite and digested all kinds of food. The reduction products of bilirubin were discussed and spectroscopically illustrated. Evidence was given of the identity of normal and pathological urobilin. The pigment of the fæces, stercobilin, was usually found to be largely urobilin, but in one case appeared to be mainly hydrobilirubin. Intermediate reduction products are also probably present in fæces. The relation of the liver to urea was also considered and the results obtained by Neucki, Pawlow, &c., with an Eck's fistula detailed. The power of the liver to detain and destroy poisons introduced into or manufactured in the alimentary canal was also pointed out.

Remarks were made by the PRESIDENT, Dr. HUNTER, and Dr. WATSON, and Dr. W. B. RANSOM replied.

CARDIFF MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Surgical Measures in the Aged.

THE usual monthly meeting of this society was held on May 8th, Dr. EDGAR JONES, President, being in the chair.

Mr. HIER EVANS showed a Case of Diffuse Scleroderma in a boy aged nine years. No other members of the family suffered from a skin disease.

Dr. RHYS GRIFFITHS showed for Dr. HARDYMAN: (*a*) A very severe case of Pott's Fracture saved by conservative treatment, a large wound having been subjected to oxygen treatment; and (*b*) a Roentgen photograph taken by Mr. Allen showing Injury to the Internal Condyle of the Humerus.

Mr. J. LYNN THOMAS showed: (*a*) A Case of Bazin's Malady in a girl aged nineteen years. The symptoms coincided with Mr. Hutchinson's description of the disease. It was confined to the region between the knees and ankles, symmetrical, and had been treated for some months as a case of syphilis. The patient gave a perfect counterfeit synopsis of the manifestations of secondary syphilis. On Boxing Day, 1894, she was ravished (*sic*) in the train by an unknown man. She subsequently—about two months later—had "sores on the genitals," "skin eruption," "loss of voice," and "this disease on my legs." On close examination she turned out to be a *virgo intacta;* the "sores" were retention cysts on the labia minora, the "sore-throat" depended upon simple laryngitis to which she was liable, the "skin disease" was acne, and the "disease on her legs" was what Mr. Hutchinson has designated "Bazin's malady." (*b*) A series of Roentgen Photographs illustrating Foreign Bodies in the Hands, Fracture of the Forearm, Disease of the Elbow, and a Fœtus five months old, showing three rows of Ossific Centres in the Vertebral Column.

Dr. PATERSON showed: (*a*) A case of Unusual Hemispasm following Hemiplegia in a Child aged two years; and (*b*) the Bulbous Extremity of a Divided Spinal Accessory Nerve.

Dr. ALFRED SHEEN showed a man with a very Extensive Keloid on the Back following a Burn.

Dr. A. W. SHEEN read a paper on Surgical Measures in the Aged. The paper emphasised the importance of antiseptic surgery in operations and the urgency of allowing aged patients to get up soon after any injury or operation. Confinement in the recumbent position and carelessness in asepsis or antisepsis are frequent avoidable causes of death in the aged.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

A Few More Words on Strophanthus.—Exhibition of Cases and Specimens.—Lantern Demonstration.

THE eighth meeting of this society was held on May 6th, Dr. ARGYLL ROBERTSON, President, being in the chair.

Dr. G. W. BALFOUR read a paper entitled "A Few More Words on Strophanthus." He remarked on the importance of the subject and stated that they had been asked to put faith in strophanthus on the strength of a series of cases in which the employment of the drug was followed by the disappearance of dropsy, and in which the pulse tracings showed an apparent improvement in the pulse-rate and blood pressure. But the like, he said, happened before without either strophanthus or digitalis and happened daily even now. History, he thought, showed that many, if not most, cardiac cases in hospital required no treatment but rest. Drugs only were of permanent value which increased the elasticity of the myocardium, and this action could only be permanent when accompanied by a corresponding improvement in the general metabolism. This action was typically preserved by digitalis, the elasticity in the myocardium was increased, and this was accompanied by a rise in the general blood pressure. The only other member of the digitalis group which had succeeded in obtaining general recognition was strophanthus, but its action was essentially different from digitalis. Therapeutically it was used to prolong the cardiac diastole and to increase the contractile energy of the myocardium. Its disadvantages were its twofold action on the heart (small doses prolonging the diastole and large doses arresting the heart in systole) and its excessive energy as a poison. Again, strophanthus acted 3000 times more powerfully on the heart than digitalis and 100 times less powerfully than digitalis on the muscles of the arterioles. Thus any rise in the blood pressure produced by strophanthus was due to the systole of the heart and no action was produced similar to that seen in a case of bradycardia, and the rise of blood pressure was thus evanescent, and from the absence of any improvement in the metabolism of the myocardium the stimulating action of strophanthus must tend to exhaust instead of strengthening. Dr. Balfour next glanced at the action of strophanthus on the nervous mechanism of the heart, and maintained that it produced an effect typically that of a heart dying from exhaustion. Finally, he maintained that the action of strophanthus, like all its congeners of the Apocynaceæ, was that of a cardiac poison and not a cardiac tonic; in therapeutic doses it stimulated the heart to increased action, and by calling upon its reserve of energy, without improving its metabolism, it caused death in diastole from exhaustion. The more feeble the heart the greater the risk attending its action. Strophanthus he considered at all times an uncertain and dangerous drug to employ and one entirely unworthy to be called a remedy.—Dr. GRAHAM BROWN, Dr. JAMES RITCHIE, and others took part in the discussion.

Dr. ALEXIS THOMSON showed for Mr. ANNANDALE:—1. A patient after Plastic Operation of the Face for Deformity caused by Rodent Cancer. When he first came under notice he had been repeatedly operated on for the cancer, a gap being present in the position of the nose. The gap was filled up with tissues from the upper lip. The present drawback was that there was a strong growth of hair from the nose. 2. Two cases of Perforating Ulcer of the Foot. In the first case the posterior tibial nerve had been stretched and the ulcer had completely healed. The patient suffered from early tabes dorsalis. The second case was in an early stage. The ulcer was on the plantar surface of the great toe. The ulcer was anæsthetic and analgesic. Symptoms of peripheral neuritis were present. 3. A patient after operation

Digitized by Google

for Perforated Gastric Ulcer. The patient while walking was suddenly seized with pain in the abdomen about the region of the umbilicus. The pain was very severe and when first seen by his medical attendant he was manifestly very ill. During the evening he vomited and was sent to the hospital as suffering from intestinal obstruction. There was, however, no obstruction, and the diagnosis seemed to lie between perforated gastric ulcer and appendicitis. No evidence of appendicitis could be made out. There was a history of slight dyspepsia before the attack of severe pain. The abdomen was opened and the peritoneum was found to contain gas and turbid fluid, milk. egg, &c. Yellow lymph was present on the peritoneal surface of the stomach and intestine. An ulcer was found in the anterior wall of the stomach with a circular perforation. The ulcer was invaginated and a drainage-tube was left in the abdomen and the abdominal wound stitched up. The bowels moved next morning after a saline purge. There was some delirium, as was frequently seen in such cases, but the patient made an excellent recovery, and was now in good health. Mr. Thomson remarked that six days ago he had operated on a similar case in Mr. Annandale's wards; the patient was going on well.

Dr. JAMES CARMICHAEL showed a child seven years old. She had been admitted to the Sick Children's Hospital on account of inability to walk. Three months previously she had had an attack of bronchitis. On recovery from this she was found to be unable to walk. She now walked with a "waggling" gait and the attitude of a case of pseudo-hypertrophic paralysis. The whole muscular system was in a feeble state. The feet were markedly flat. No evidence could be found of disease of the nervous system. The electrical reactions of the muscles were normal.

Mr. DAVID WALLACE showed two cases with unusual features. The first was a man twenty-three years of age who was admitted to the Royal Infirmary suffering from tuberculous bone disease for which one foot was amputated. On returning to report himself a swelling was found on the right side of the head. Fluid was diagnosed. Under chloroform an abscess was opened. A sequestrum was found which, when touched by the examining finger, disappeared into a cavity between the skull and the dura mater. It was a case of tuberculosis perforans of the skull, a somewhat rare condition, and had given rise to no symptoms. The patient made an excellent recovery. The second case was that of a man aged thirty-six years who was trephined. While carrying wood he fell and was found unconscious. He was removed to the infirmary, where he was found to be in a very drowsy state with a wound over the left parietal region. The pulse was 42. The pupils were equal. He vomited, and the pulse rose gradually to 62. He was in a drowsy condition, breathing heavily, but not stertorously. The following day the pulse was quicker and the temperature rose to 102° F. He seemed more drowsy, and there was some paresis of the right arm. He had the appearance of cerebral irritation. Next day as he seemed to be getting worse Mr. Wallace operated. A portion of the left parietal bone was found and a circle of bone removed, but no hæmorrhage was discovered. The coronal suture was, however, noticed to be separated. Mr. Wallace then trephined on the right side, but found no gross hæmorrhage, merely small extra-dural hæmorrhage. The patient gradually became conscious and made a good recovery. In this case there seemed to have been first concussion followed by reaction, with the production of small hæmorrhages.

Dr. NORMAN WALKER showed a patient to whom Warts had been communicated by shaving.

Mr. CAIRD gave a Lantern Demonstration illustrating the Pathology of the Appendix Vermiformis.

Dr. NORMAN WALKER showed microscopic specimens—(1) from a case of Ringworm of the Scalp in an Adult—a very uncommon condition; and (2) the Germs said to be responsible for Eczema. They were found in mulberry-shaped collections.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases, Specimens, and Photographs.

THE concluding meeting of the session was held on May 8th, Dr. W. G. DUN being in the chair.

Dr. WALKER DOWNIE showed an infant the subject of Membranous Occlusion of the Left Nostril. The child was brought to hospital on account of noisy respiration and of inability to retain the nipple in the mouth when taking the breast, a condition which had been present since birth. Examination discovered a membranous diaphragm closing the left nostril less than a quarter of an inch within the orifice. There were evidences of syphilis in the child and Dr. Downie was disposed to regard the occlusion of the nostril as the result of an ulcerative process which had existed in intra-uterine life.

Dr. LINDSAY STEVEN showed a man twenty-two years of age who after a severe attack of enteric fever in May, 1895, developed three weeks after convalescence an extreme Spastic Condition of the Left Upper Limb especially marked in the flexors of the digits and elbow; a similar but less extreme condition appeared in the left foot. Sensation was undisturbed; the tendon jerks were exaggerated; there was no reaction of degeneration, and no history or evidence of syphilis. Dr. Steven had no doubt that the lesion was situated in the upper segment of the left motor tract, but its nature he regarded as very uncertain. He leaned rather to the view that it was thrombotic, leading to a gradual sclerosis in the motor cortical area.—Dr. STEVEN also demonstrated four cases of Enlargement of various Groups of Lymphatic Glands for the purpose of illustrating his opinion that in many such cases the distinction that ought to be made between true Hodgkin's disease and other lymphatic enlargements was not made. The most interesting member of the group was a lad aged nineteen who, after suffering from enlargement of the cervical and axillary glands for some months, began to develop evidence of paralysis of the third cranial nerve on the right side with, afterwards, great difficulty in walking and a tendency to fall backwards when not supported although the lower limbs were not paralysed. The case was described as a genuine case of Hodgkin's disease, with formation of a nodule or nodules exercising pressure on the central nervous system; there was no splenic enlargement. Dr. Steven concluded this part of his demonstration by showing a lympho-sarcomatous growth from the mediastinum. The malignant process had extended to the pleura, and large numbers of nodules had developed along the surfaces of the ribs and also in the subcutaneous tissue.—Dr. STEVEN also showed the Liver from a case of Congenital Absence of the Common Bile Duct removed from the body of a child who had died aged five months. The child had been jaundiced from birth, but had appeared in all other respects to be a perfectly normal child. On the morning of death the child had seemed to be dull and listless and cried when moved. Death occurred suddenly from a large hæmorrhage into the intestine. Post-mortem examination showed the absence of the common bile duct, the cystic duct terminating in a filamentous cord. The normal hepatic ducts were present, the capillary ducts in the liver being distended with bile. The liver itself was the seat of a fine cirrhosis. Dr. Steven drew attention to the rarity of the case as a complete record and to the comparatively long time which the child lived in apparently complete health and happiness.—Dr. R. M. BUCHANAN discussed the case and briefly described two similar cases which he had seen at the Royal Hospital for Sick Children.

Dr. C. O. HAWTHORNE showed the Suprarenal Capsules from the body of a woman aged fifty, the capsules being enlarged and almost completely caseous. The patient had been the subject of phthisis pulmonalis and there had been marked pigmentation of the skin of the trunk. The face was quite free from undue pigmentation, and there was no noteworthy darkening of the skin of the axillæ or of the genitals. There were no patches on the buccal mucous membrane. A contrast, however, was appreciable between the skin of the palms of the hand and that of the dorsum of the hand and the front of the forearm, there being in the last-mentioned situations a faint but distinct walnut-tinged colour which terminated abruptly at the base of the palm. This, together with the pigmentation of the trunk and some few but not severe attacks of vomiting, had been regarded as rendering a diagnosis of Addison's disease probable, and the patient's sudden death and the post-mortem examination confirmed this view.—Dr. HAWTHORNE also showed photographs and drawings of a case of Leucoderma. The patient was a woman aged forty-three years and the subject of symptoms pointing to chronic pathological changes in the lumbar enlargement of the spinal cord. There was also extensive brown pigmentation of portions of the trunk and limbs with intervening areas of skin almost entirely free from pigment. It was specially noteworthy that the distribution of this condition was almost exactly symmetrical, there being, for example, a white patch

Digitized by Google

over each elbow, each hip, and in the lower half of each forearm. Dr. Hawthorne suggested that this distribution must be taken as supporting the view that leucodermic patches are essentially dependent upon changes in the nervous system.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Suppurative Pericarditis treated by Drainage.—Leucocythæmia.—Empyema.—Exhibition of Cases.

A MEETING of this section was held on May 8th, Dr. WALTER G. SMITH being in the chair.

Dr. O'CARROLL read an account of a case of Suppurative Pericarditis secondary to Pneumonia which had been treated by free and constant drainage. The pericardial cavity gradually contained less and less pus, but the patient died from asthenia two months afterwards, and the walls of the pericardial cavity were then found to be adherent everywhere except in front, where there was about a drachm of pus.—Dr. M. A. BOYD related the particulars of a case in which he drew off four ounces of serous fluid and the patient recovered. The temperature might be normal though there was pus in the pericardium. In children broncho-pneumonia often preceded the collection of fluid in the pericardium; he thought that paracentesis should be resorted to more frequently than at present in cases of pericarditis in children.—Dr. HEARD drew attention to the observation of Dr. Ewart that a patch of dulness might be detected at the inner side of the angle of the left scapula at the base of the left pleura as an early symptom in these cases.—Dr. DRURY asked what was the exact site selected for the operation. It had been recommended some time ago to tap the pericardium as close as possible to the left margin of the sternum in the fourth interspace, but he had examined a large number of subjects in the dissecting-room and had found that in a considerable proportion of cases either the internal mammary artery or vein would be wounded by such a proceeding.—Dr. FINNY said that he had only met with one case of suppurative pericarditis requiring operation. He tapped the pericardium one inch outside the sternum, between the fourth and fifth ribs, and drew off eight ounces of purulent fluid, giving immediate relief, but a second attempt to perform the same operation with a larger needle did not succeed, as for some unaccountable reason he failed to reach the pericardium. The post-mortem examination revealed a large collection of pus in the pericardium. He thought that pericarditis was comparatively a rare disease, and that extensive pericardial effusion was very rare, the consequence being that very few cases required to be tapped, but tapping should be resorted to when the symptoms did not yield to other forms of treatment, especially when the effusion was believed to be purulent.—Dr. O'CARROLL, in reply, said that there was no infection of the left pleura, as the fluid which it contained was a clear serous fluid due to the cardiac failure which occurred at the end of the patient's life. Though he had carefully examined the patient's chest he had not remarked the symptom referred to by Dr. Heard. In making the puncture he had selected a point in the fourth space a thumb's breadth internal to the nipple line.

Dr. CRAIG read a short paper on Leucocythæmia and exhibited stained blood films and photographs of a case of the lymphatic type of this disease. The patient had died in hospital after an acute illness of two months' duration, his symptoms being general enlargement of all the lymphatic glands, pallor, severe epistaxis, diarrhœa, temperature varying from 99° to 103°F., dyspnœa, slight increase in size of spleen and liver, but no tenderness over the bones. In the blood there was a diminution in red cells to at least one-third of the normal number and an absolute and relative increase of the leucocytes, so that the proportion of white to red averaged about one to twenty. Dr. Craig drew attention to the recent description by Kanthack and Hardy of the leucocytes found in normal blood, and said that in his case all the forms of white cells could be seen, although the increase was entirely due to the presence of lymphocytes. He pointed out that a purely lymphatic form of leukæmia was rare, that its victims were among the young, and that the disease generally ran an acute and rapidly fatal course. In the present instance the patient was an Italian nineteen years of age, and the illness terminated fatally within two months from its onset. The severe epistaxis and persistent diarrhœa required symptomatic treatment so that arsenic was not given a fair chance and bone-marrow was not tried.—The CHAIRMAN thought that the clinical significance of the various leucocytes was still very doubtful. He stated that the continuous use of arsenic in chronic cases was not devoid of danger, as peripheral neuritis might ensue; he also mentioned the great chemical changes that occurred in the urine in this disease, the uric acid and the xanthine bodies being increased.—Dr. BOYD mentioned that he had treated a case of the lymphatic form in which there was marked tenderness of the tibiæ, sternum, and ribs. Under arsenic there was distinct improvement (proportion of leucocytes 1—300). The patient was then put on bone-marrow, but a relapse occurred (leucocytes 1—20). On resuming the arsenic treatment improvement again took place and the patient returned to the country, where, however, he relapsed again and died in three or four months.

Dr. A. R. PARSONS read notes of a case of Extensive Empyema.—The CHAIRMAN said that in such cases the heart was generally the first organ to return to its normal position. After aspiration the effects of the diplococcus of pneumonia seemed more amenable to treatment than those of the streptococcus, so that the examination of the pus was of the greatest consequence. He agreed with Dr. Parsons that a peculiar tympanitic note on percussion and roughness on breathing were often the first symptoms in such cases.

Dr. A. R. PARSONS also exhibited a case of Atresia Auris and Unilateral Facial Paralysis occurring in a female patient and a case of Hemichorea.

Reviews and Notices of Books.

Abdominal Tumours and Abdominal Dropsy in Women. By JAMES OLIVER, M.D., F.R.S. Edin., Physician to the Hospital for Women, Soho-square, &c. London: J. and A. Churchill. 1895.

THIS little book consists of 281 pages of large print, divided into twenty-six chapters, in which various swellings met with in the abdomen, ranging from pregnancy to cancer of the liver, are more or less fully considered. It will be seen that while several of the tumours described are those more particularly belonging to the department of gynæcology, a large number, such as tumours produced by enlargement of the liver, enlargement of the gall-bladder, tumours of the pancreas, and tumours connected with the spleen and kidney, belong to general medicine. We think, however, that the author has done right to include them, as the diagnosis of any particular abdominal tumour involves to some extent a knowledge and exclusion of all the rest.

Contrary to the usual practice, the author does not give us any information as to the intention or aim of the work, for he does not supply a preface. The book very properly begins with the diagnosis of pregnancy in its various phases. It is hardly possible to lay too much stress on the need for acquiring a practical familiarity with all the physical signs of pregnancy, for there is no subject in which mistakes are more frequently made—mistakes which necessarily tell to the disadvantage of those making them, as well as of their patients.

In what appears to be intended to be a monograph it might perhaps be said that some of the cases given under the heading Utero-gestation are a little trite and elementary—e.g., Case 4, on page 10, entitled Conception occurring while Menstruation was held in Abeyance by Lactation. This is a matter of frequent occurrence; no doubt a case of this kind is instructive to a student beginning to work at the subject, but in writing for those who may be presumed to have had a certain amount of general experience so elementary a piece of information would seem a little superfluous. The same may be said of Case 5, entitled Pregnancy in a Woman

Digitized by Google

who ever since the Establishment of Menstruation had Menstruated with great Irregularity.

We observe in the section devoted to Hydatid Mole that the author says that "on vaginal examination portions of the mole may be found hanging through the cervix." This is certainly contrary to the general experience except in cases where the mole is actually in process of being spontaneously expelled. In the chapter on Fibroid Tumours of the Uterus, Case 7, Uterine Fibroid producing Retention of Urine after the Menopause, illustrates what has become more generally recognised of late—viz., that it is by no means rare for these tumours to give trouble even after the change of life.

In Chapter VII., on Hæmatometra and Hydrometra, which, by the way, is a very short one, only consisting of two and a half pages, the author recommends for the treatment of imperforate hymen that a small opening should be made and after the bulk of the fluid has escaped that the opening should be enlarged, but does not say in what way the opening is to be made, whether by the knife or scissors or aspirating needle, or by the method which is generally considered best nowadays—viz., with Paquelin's cautery. In speaking of Ventral Hernia he says in mild cases much good may accrue from galvanism and the administration of tonics, but in others a properly adjusted abdominal belt is imperative. He omits any mention of the operative treatment of this condition.

The American Year-Book of Medicine and Surgery; being a Yearly Digest of Scientific Progress and Authoritative Opinion in all Branches of Medicine and Surgery, drawn from Journals, Monographs, and Text-books of the leading American and Foreign Authors and Investigators. Under the general editorial charge of GEORGE M. GOULD, M.D. London: The Rebman Publishing Co., Limited. Philadelphia: W. B. Saunders. 1896. Price 38*s*.

THIS handsome and bulky volume forms a welcome addition to the somewhat extensive series of year-books which aim at presenting a critical digest of contributions to every branch of medical and surgical literature that have appeared within the preceding twelve months. The work before us deals with the period from July, 1894, to June, 1895, and it is difficult to know which to admire most—the research and industry of the distinguished band of experts whom Dr. Gould has enlisted in the service of the year-book or the wealth and abundance of the contributions to every department of science that have been deemed worthy of analysis. Publications such as this serve to bring home to us the fact that in all parts of the world there is constantly increasing activity in ever-widening circles for the advancement of scientific knowledge and the promotion of sound medical and surgical practice. As regards the work itself it is much more than a mere compilation of abstracts, for as each section is entrusted to experienced and able contributors the reader has the advantage of certain critical commentaries and expositions, where such seem to be needed, proceeding from writers fully qualified to perform these tasks. It would be impossible to treat such a work as if it were an ordinary manual or text-book; there is no single critic who could presume to offer an opinion as to whether the matters dealt with in each and every section are of adequate importance or whether they have been suitably noticed. It may, however, be taken as certain that as regards method of arrangement of subjects, their proportionate distribution, and the lucidity with which they are treated this year-book is of much excellence. The following is a list of the departments and of the contributors to them. General Medicine: Dr. W. Pepper and Dr. A. Stengel; Surgery, Dr. W. W. Keen and Dr. J. C. Da Costa; Obstetrics, Dr. Barton C. Hirst and Dr. W. A. Newman Dorland; Gynæcology, Dr. J. M. Baldy and Dr. W. A. Newman Dorland; Pediatrics, Dr. L. Starr and Dr. Thompson S. Westcott; Nervous and Mental Diseases, Dr. A. Church and Dr. H. J. Patrick; Dermatology, Dr. W. A. Hardaway and Dr. C. F. Hersman; Orthopædic Surgery, Dr. Virgil P. Gibney and Dr. Homer A. Gibney; Ophthalmology, Dr. H. F. Hansell and Dr. C. F. Clark; Otology, Dr C. H. Burnett; Diseases of the Nose and Larynx, Dr. E. Fletcher Ingalls and Dr. T. Melville Hardie; Pathology and Bacteriology, Dr. J. Guiteras and Dr. D. Riesman; Materia Medica. Experimental Therapeutics, and Pharmacology, Dr. H. A. Griffin and Dr. Van Horne Norrie; Anatomy, Dr. C A Hermann; Physiology, Dr. G. N. Stewart; Hygiene, Medical Jurisprudence, and Chemistry, Dr. H. Leffmann. The book is furnished with an admirable index—a *sine qud non* in a work of reference—and is also illustrated by engravings and coloured plates reproduced from articles quoted. It is emphatically a book which should find a place in every medical library and is in several respects more useful than the famous "Jahrbücher" of Germany. It has, however, one blemish which to many may perhaps seem but venial. Much as we admire this very excellent review of medical and surgical progress we cannot refrain from regretting that the learned editor—himself a lexicographer—should have adopted some of the "new spelling," which, although advocated by some very eminent men, seems to us to be a retrograde step and one destructive of etymology. Dr. Gould has done this, he says, in his preface, "in the interest of much-needed brevity and simplicity"; but although he may succeed in familiarising us with such elisions as occur in the words "chlorid," "chlorin," "iodid," "iodin," "quinin," "aceton," just as we have long been used to "labor," "color," and "hemorrhage," it will take longer for even the mildest purist to be reconciled to "anemia," "hemoglobin," "uremia," "hemoptysis," "pyemia," and the even more startling "edema," and "esophagus," which are but samples of the manner in which the diphthong is here ignored. Nor can we pretend to prefer "goiter," "center," "pathologic," "histologic," or "physiologic" to the recognised spelling of the words these terms represent. Has Dr. Gould in view the further extension of this system in successive year-books, and having accustomed us to these samples is he meditating a further driving in of the wedge and the elision of all mute consonants also? If so, we fear that what may be a gain to the cause of phonetic spelling will be a loss to literary style and accuracy, and Dr. Gould himself may have to remodel his famous dictionary.

Surgical Pathology and Morbid Anatomy. By ANTHONY A. BOWLBY, F.R.C.S. Eng., Assistant Surgeon to St. Bartholomew's Hospital. Third edition. London: J. & A. Churchill. 1895. Pp. xxiii. and 640. Price 9*s*.

PATHOLOGY holds at the present time a place very different in importance from that which it occupied twenty years ago. The constant progress that has been made in all its departments of late years has converted it from one of the minor branches into the chief branch of medical science, for it is only by a correct pathology that we can prevent disease; and on a true knowledge of pathology therapeutics, to be successful, must be based. The volume before us is one of the most satisfactory of the smaller text-books on a subject often too scantily treated in the ordinary manuals of surgery. In noticing the first edition of this work in 1888 we spoke with approval of the care which had evidently been bestowed upon it, and we are glad to see that this the third edition is an improvement even on the two preceding issues. The descriptions of pathological conditions are accurate and concise, yet conciseness has not been gained at the expense of accuracy and the descriptions are sufficiently full for any student's requirements. All parts of the work have been brought

Digitized by Google

up to date, but the present edition differs from its predecessors chiefly in the fuller account which has been given of bacteriology, and this is due to Dr. Kanthack, Lecturer on Pathology at St. Bartholomew's Hospital, who has rewritten the chapter on Micro-organisms in their relation to Pathological Processes, and has also added to the information regarding pathogenic bacteria in various parts of the book. Twenty new illustrations have been added to the 185 present in the second edition. The book may be safely recommended as a trustworthy handbook to the science of surgical pathology.

Pediatrics: the Hygienic and Medical Treatment of Children By THOMAS M. ROTCH, M.D., Professor of the Diseases of Children at Harvard University. Two Vols. Edinburgh and London: Young J. Pentland. 1896.

FROM several points of view this is one of the most important works on the diseases of children which has appeared for many years. It differs from previous text-books in the large amount of space devoted to the natural development of children from birth to puberty and to the question of natural and artificial feeding, and also in the remarkable wealth and excellence of its illustrations. These latter are for the most part good mechanical reproductions of photographs, but there are also a number of accurately coloured plates. The book is almost over-illustrated, but this, after all, is a fault in the right direction, and it would be hard to find a work of the kind in which photography has been more successfully employed.

The text takes the form of lectures, apparently as delivered at Harvard University, and they are fifty-three in number. The first four are devoted to an account of the fœtus at term and the normal development of the infant, nor can even this large amount of space be considered too much when it is reflected how widely the anatomy and physiology of the infant differ from those of the adult. The subject is one which is usually passed over in a short introductory chapter, but Professor Rotch has here collected facts and statistics from the literature of all countries so as to furnish a valuable work of reference. And in this he has done good service, since knowledge of this kind must lie at the root of the successful recognition and treatment of children's diseases. After a good practical lecture on nursery hygiene he passes to the subject of infant feeding, to which no less than six lectures are devoted. This is a question of which Professor Rotch has made a very special study, and there is no man more qualified than he to write on it. To him is due the establishment of milk laboratories in America, the first having been opened in Boston in 1891. The amount of detailed care which has been spent on the matter is marvellous, and a perusal of the account here given may well make Englishmen blush that we are so far behind America in our artificial feeding. The most rigid care is taken in assuring purity of source of the milk and in preventing its subsequent contamination; at the laboratory it is separated by a centrifugal apparatus, sterilised, and re-combined in accordance with the physician's prescription. The physician can order any percentage of fat, sugar, and proteid within reasonable limit which he may choose just as he would order a prescription at a druggist's. So novel and excellent a departure is well worthy of imitation in this country, and, indeed, there are already signs of its being taken up. But for the benefit of that majority of mankind which has no milk laboratory within reach Professor Rotch gives complete directions for the home modification and sterilising of milk by means of simple and inexpensive apparatus which should prove of great practical utility. A special chapter on premature infants and their treatment completes this part of the book.

The succeeding part, dealing with the diseases of children, is also of considerable though unequal merit and bears throughout the stamp of originality, based as it is largely on the author's own experience. More than seventy pages are devoted to a study of the blood in childhood, in health and in disease, a point to which Professor Rotch justly attaches great importance. The account is very full and excellent and is followed by a full bibliography of the subject, which will make it a valuable work of reference for some time to come. The diseases and malformations of the newborn are treated in a separate section of three chapters. The order in which the systematic diseases of children are discussed is occasionally erratic. It is difficult to perceive the advantage of separating diphtheria and epidemic influenza from the specific fevers and treating the first-named under the heading of diseases of the mouth, nose, and pharynx, while influenza figures amongst the "unclassified diseases." This, however, matters little so long as the accounts given are good, which, indeed, they mostly are, though the different sections are, as we have said, not all of equal merit. The chapter on rickets may be instanced as inadequate to the importance of the disease—at least to the mind of an English physician. A valuable feature of the book lies in the frequent introduction of short accounts of illustrative cases. Temperature charts are also largely reproduced, but in a form which renders them strange and unpleasing to the eye, for the morning temperature is inserted vertically under that of the preceding evening, an arrangement which is at variance with fact and has nothing to recommend it. The worst which can be said of the book is that it is not all of the same great excellence as the introductory part. But Professor Rotch has produced a work which must have a standard place in the literature of children's diseases, and which no one studying the subject can afford to neglect.

Klinische Vorlesungen über Syphilis. Von Dr. E. VON DÜRING, Professor für Dermatologie und Syphilis an der Kaiserlichen Medizinschule in Konstantinopel. (*Clinical Lectures on Syphilis.* By Dr. E. VON DÜRING, Professor of Dermatology and Syphilis at the Imperial School of Medicine, Constantinople.) Hamburg und Leipzig: L. Voss. 1895. Pp. xvi. and 320.

THESE twenty-two lectures were delivered in French at the Imperial School of Medicine at Constantinople and have been translated into German for the use of the medical men attending the Haïdar-Pascha Hospital. Though the author expressly disclaims in his preface that these lectures form a complete text-book, we cannot but think that the work contains a very full and able exposition of the present knowledge of syphilis. As might be expected from Dr. Düring's position the skin affections caused by syphilis receive a greater share of attention than is usually accorded to them in most treatises on the subject; the author points out that so far as the skin at least is concerned no sharp line can be drawn between secondary and tertiary affections, that the manifestations attributed to these stages are often so mingled that they cannot be satisfactorily separated. Dr. Düring looks upon the papule as the fundamental lesion in all syphilides, and considers that all the other forms, such as the squamous, the vesicular, and the ulcerating, have developed from the papule. The author recognises a syphilitic neuritis and thinks that this condition accounts for many of the chronic pains which so often occur among the sequelæ of syphilis. The absence of any illustrations is accounted for by the work being merely a reprint of lectures, and we can understand that they were not essential for those for whom the book was intended—namely, the students attending the author's clinic; but it detracts somewhat from the value of the work for the ordinary reader.

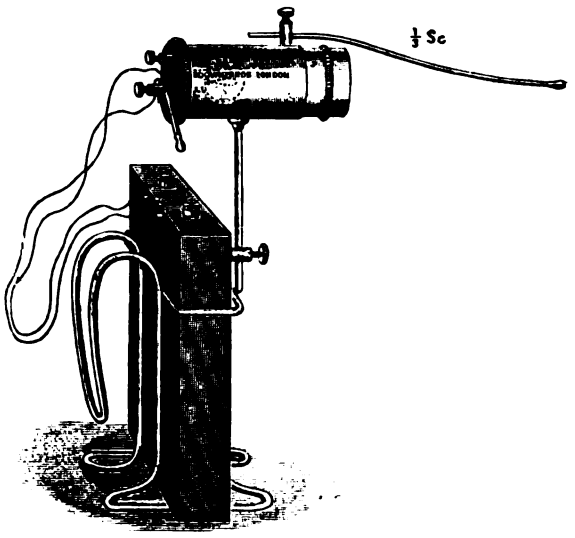
New Inventions.

ELECTRIC HAND LAMP.

A FOUR-VOLT accumulator, carried in a light wire stand, is the source of electric power. The lamp, a small 3½-volt incandescent one, is brilliantly lighted by a current of rather more than half an ampère. The beam of light, rendered parallel, convergent, or divergent by a three-quarter inch focal length bi-convex lens in a sliding mount, can be so directed

FIG. 1.



Stand, Accumulator, and Lamp, with Wire for Swab attached.

as to brightly illuminate the fauces without falling also upon the lips or teeth. A binding-screw on the top of the lamp case forms an attachment for the end of a wire swab (as shown in Fig. 1) for bacterioscopic examination, thus leaving the other hand available for the tongue depressor. The incandescent lamp is, of course, somewhat overworked, but it is inexpensive and is so mounted as to be easily renewable.

FIG. 2.

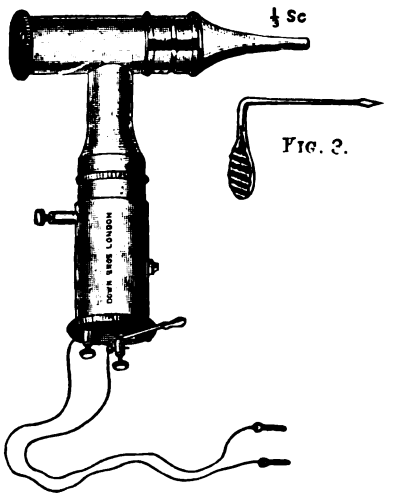


FIG. 2.

Lamp, with the Otoscope attached, and the Myringotome.

The lamp is detachable from the pin which fixes it to the front of the stand. After two years' use the accumulators are still in excellent working order.

The lamp is furnished with a flange for the attachment of a 'Brunton's" otoscope (Fig. 2) modified by having a slot cut in it so as to permit of the use of a specially shaped myringotome (Fig. 3) through it. The membrana tympani is very well illuminated by the electric lamp, and operation upon it is rendered easy. The lamp has been made for me by Messrs. Down Brothers, 5 and 7, St. Thomas's-street, Borough, S.E.

E. O. HOPWOOD,
Resident Medical Officer, London Fever Hospital, Islington.

RED CROSS PERFUME GERMICIDE.

WE have received from the Red Cross Germicide Company, Gresham-street, E.C. a sample of their "perfume germicide" and a convenient form of inhaler. The germicide consists of an alcoholic solution of a fragrant essential oil. The essential oil separates on addition of water, which develops its agreeable smell considerably. The inhaler in fashioned on the principle of an ordinary wash-bottle—i.e., it consists of a container with two tubes passing through the cork. One tube dips below the surface of the fluid in the container and the other ends at a point above the level of the fluid. By inhaling through tube No. 2 air is drawn through tube No. 1, and the fluid reaches the lungs charged with the volatile constituents of this fluid. In tube No. 1 is a small ball valve to prevent regurgitation in cases of coughing. The apparatus affords a handy and inexpensive method of inhaling medicated vapours, although there is nothing very new about it. It was suggested by Dr. O. Siemon of Cottbus, Germany.

A NEW MILK STERILISER.

WE have received from Mr. J. L. Aymard of Ipswich a new and simple apparatus for the sterilisation of milk by heating it rapidly and effectually in such a manner that it is not altered by evaporation. It consists of two parts—an ordinary saucepan to hold boiling water for the supply of steam and the milk container, which is surrounded by a tin plate cylinder or jacket, the intervening space of about half an inch in width being filled with steam when in use. This cylinder is open at the bottom, fits closely into the top of the

saucepan, and has a lid, so that the milk container is everywhere surrounded by steam except where its spout projects externally. The manner of using it is very simple. Some water having been made to boil in the saucepan the jacketed milk container is placed in position, and the whole is set over a good spirit-lamp or fire for about five minutes, which is sufficient to bring the milk to a temperature exceeding 200° F. without giving it the disagreeable flavour due to over-heating or "burning" which is so common with ordinary boiled milk. This apparatus enables milk to be very quickly sterilised for the use of an infant in small quantities as required, and there is of course no separation of the cream, so that the result is better than when a number of small bottles of milk are treated at one time, according to the usual practice, for when these bottles become cold the cream rises and sticks around the narrow necks. An important advantage of sterilisation is that it prevents any risk from the pathogenic organisms so frequently conveyed by milk, such as those of tubercle, scarlet fever and enteric fever. A thermometer is not essential, but it can be supplied if required. The sterilisers are made in sizes capable of treating amounts of milk varying from three-quarters of a pint to six gallons; the prices range from 3s. 6d. to £5 5s., the latter including a portable furnace and copper. The makers are Aymard's Patent Steriliser Company, 19A, Coleman-street, E.C.

THE LANCET.

LONDON: SATURDAY, MAY 23, 1896.

THE wheels of progress at the Royal College of Surgeons of England, which had been clogged and seemed likely to remain at a standstill for an indefinite period, have been freed from some of the impediments which had caused the deadlock and are once more steadily though deliberately revolving. The overwhelming vote of the Fellows of the College in favour of the principle of representation of Members of the College on the Council recorded at the half-yearly meeting of the Fellows in January last ensured the defeat of the report of the Deputation Committee, which virtually recommended the Council not to make any concession either to the Fellows or to the Members and the acceptance for the moment of an amendment moved by Mr. TWEEDY and seconded by Mr. RIVINGTON to this effect: "That the recommendations of the Deputation Committee be not adopted, but that a poll of the Fellows be taken respecting the motion passed at the general meeting of Fellows on Jan. 2nd in favour of giving to the Members of the College direct representation upon the Council, and that a committee be appointed to prepare for the approval of the Council an elucidatory statement of the subject in question, together with the interrogatories which shall be submitted to the Fellows." This amendment was carried by 12 votes to 11, but when put as a substantive motion it was moved by Sir WILLIAM MACCORMAC and seconded by Mr. BRYANT: "That before the Fellows are addressed upon the subject the Council do take into consideration at an early date the question whether Members should or should not be directly represented on the Council." It will be observed that the terms of this resolution were in themselves ambiguous, and, naturally interpreted, imply that the Fellows were to be addressed as soon as the Council had taken the subject of the representation of Members on the Council into consideration, and, therefore, that the resolution was not antagonistic to the poll of the Fellows proposed in the resolution of Mr. TWEEDY. When put to the vote twelve members of the Council voted for the resolution and eleven against, one vote having been transferred from one side to the other. The resolution, being then put as a substantive resolution, was carried, and set aside Mr. TWEEDY'S motion. At the March meeting the Council took the subject of the representation of Members of the College on the Council into consideration, with the result that the following resolution, moved by Sir WILLIAM MACCORMAC and seconded by Mr. BRYANT, "That, as the members of this Council represent the body corporate of this Royal College and consequently its Members as well as its Fellows, it is the opinion of this Council that no further representation of the Members is desirable," was carried by eleven votes to eight, two members of the Council abstaining from voting and three of reforming tendencies being absent. Thus, by a fortuitous concurrence of adverse circumstances the motion for a poll of the Fellows was lost and a feeble resolution opposed to the representation of Members of the College on the Council was carried by less than half the Council.

It was not to be expected that the reforming members of the Council would acquiesce in a fiasco which placed the question in a false position and entirely obscured the real state of opinion on the Council. Hence it was that notice was given for the re-discussion of Mr. TWEEDY'S motion and of the adverse resolution passed at the March Council meeting, and both subjects were re-opened at the meeting of the Council held on the 14th inst. Mr. TWEEDY moved, and Mr. RIVINGTON seconded, the resolution: "That a poll of the Fellows be taken respecting the motion passed at the general meeting of Fellows on Jan. 2nd in favour of giving to the Members of the College direct representation upon the Council, and that a committee be appointed to prepare for the approval of the Council an elucidatory statement of the subject in question, together with the interrogatories which shall be submitted to the Fellows." This resolution was carried by a considerable majority, thus proving that it had only been lost on a previous occasion through misapprehension on the part of some of the members of the Council. After the adoption of this resolution Mr. RIVINGTON moved, and Mr. WILLETT seconded, the motion, "That the following resolution, proposed by Sir WILLIAM MACCORMAC, seconded by Mr. BRYANT, and carried by 11 votes to 8, be rescinded—viz.: 'As the members of this Council represent the body corporate of this Royal College, and consequently its Members as well as its Fellows, it is the opinion of this Council that no further representation of the Members is desirable.'"

It was too much to anticipate that the reforming zeal of the members of the Council would extend so far as to rescind a resolution. That zeal had been exhausted when the resolution for a poll of the Fellows had been passed and could no further go. The motion was lost, not on account of the strength of the opposition, but from lack of support by those who would never have voted in favour of the resolution which it was desired to rescind. It would certainly have been better if the resolution of the Council adverse to the claims of the Members had been expunged, because it tends to complicate the position and may lead, unless adequately explained, to the loss of votes which might otherwise be recorded in favour of the representation of the Members on the Council. A great deal will depend upon the "elucidatory statement" which has to be drawn up by the committee appointed by the Council and upon the questions submitted to the Fellows. It ought to be fairly represented in the "elucidatory statement" that opinion in the Council is very evenly balanced in regard to giving the Members of the College representation on the Council, that there is no clear majority either way, and that there has not been a majority of the Council voting for the adverse resolution.

It is high time in the interests of the College that this question should be settled and settled in favour of the Members of the College. No one can find fault with the tone and temper of the Society of Members on this question. They have been moderate and dignified. It was scarcely to be expected that, desiring as the Members naturally do to

Digitized by Google

be represented by Members of the College, they should have taken the initiative and declared their willingness to be contented with representation by Fellows of the College, but, we believe, that should the Fellows of the College declare themselves favourable to the principle of representation of the Members and give a largely preponderating vote for representation by Fellows, the Society of Members would be ready to accept the decision and give to this method of representation a fair trial. It must be recollected that what is wanted is the addition to the Council of representatives of general practitioners, and no doubt these can be found both among the Fellows and he Members of the College, so that from this point of view it appears to be of minor importance whether Fellows or Members become the representatives of the Members of the College. The contentment and the unity of the great constituency which ought to be the pride of the College and its governing Council are the chief objects to be obtained, so that all connected with the institution may feel personally interested in its prosperity and work together for the common good. We firmly believe that the Fellows of the College generally will rise to this great opportunity and that they will show unmistakably that the resolution passed by the Council in a purely accidental manner does not reflect the matured opinion of the Fellows at large. We shall recur to this subject as soon as the committee has drawn up the elucidatory statement and the questions it has been appointed to prepare.

BENEDICT the Fourteenth, or MACAULAY'S "favourite Pope" according to TREVELYAN, was once asked by a nephew who wanted to follow in his uncle's footsteps what books he would recommend as best adapted to fit him for such a career. "You could not have consulted a better authority," was the Holy Father's reply. "Every year I make a list of the publications which are in all respects most worthy of perusal, particularly by aspirants such as you," and therewith handed him the last "Index Expurgatorius." The saying was even more wise than it was witty. None knew better than the able and learned Pontiff that "the most opposite opinions can make a plausible show of evidence when each has the statement of its own case, and it is only possible to ascertain which of them is in the right after hearing and comparing what each can say against the other and what the other can urge in its defence." He would even have concurred with another great thinker of our century, that, so far as the plastic and energising intellect is concerned, "a waking error is—aloof from practice—better than a sleeping truth," and that "there is no proportion between the possession of facts and the development of the mind in which they are deposited." Every schoolboy in science "is now familiar with more truths than PLATO or ARISTOTLE ever dreamed of knowing, yet" (continues the same authority), "compared with the Athenian or the Stagyrite, how few even of our masters of modern science rank higher than intellectual barbarians." Living in the middle of last century, BENEDICT the Fourteenth was in this respect at one with the most authoritative thinkers of the nineteenth century, and if on the part of the Curia he sanctioned the periodical issue of the "Index Expurgatorius" it was on grounds of which his successors in office seem not yet to have appreciated the wisdom or the wit.

On April 20th last there was affixed to the gate of St. Peter's in Rome the "Index Expurgatorius" for the year, and in it are mentioned by name at least five treatises on the subject of criminal anthropology. The medical schools, particularly at Turin and Naples, which seek to find the nexus between organisation and development, between physically conditioned propensity and moral responsibility, are directly struck at and their authors put in the pillory of the Roman Catholic Church for attempting to bring the two factors of social life into the area of inductive research. The world is assured on Vatican authority that the old explanation of intellectual and moral neuroses is the right one; that "demoniacal possession" is quite sufficient to account for the phenomena of epilepsy and epileptoid explosion; and that all attempts to investigate them on the "natural history method," as propounded and practised by HIPPOCRATES, are as useless as they are impious.

Professor LOMBROSO and his colleagues will hold themselves excused, we imagine, from regarding this denunciation of their work as amounting to more than a useful advertisement, and will be much less solicitous to notice it than to reply to such critics as Dr. MAUDSLEY and others at the last Medico-Psychological Congress. If for a moment they could be brought to consider this "decretum" of the Roman Church against them, it would be only to remind the world of the fact that similar denunciations of the modern spirit and its works have proceeded from the same quarter and been either abandoned or tacitly revoked. Between sixty and seventy years ago, for example, Pope GREGORY XVI. denounced railways as inventions of the evil one, and yet before the death of his Holiness he had to connive at their introduction into the most Catholic kingdom of the Two Sicilies, while in the next Pontificate the Eternal City saw itself connected with the seaboard and the rest of Italy by the same anathematised medium. It was Pope GREGORY, too, that fulminated against the newspaper press as another invention of the Prince of Darkness, and yet under his successor, PIO NONO, the daily and weekly journals were adopted and subsidised by the Vatican itself as the most powerful means of vindicating the apostolic cause. These are facts—facts, moreover, which justify the observation that the Roman Catholic Church in its attitude towards science seems departing from that principal which MACAULAY makes the determining cause of its vitality and its diffusion—to wit, the recognition and absorption, not the ignoring, still less the rejection, of all the forces that make for popular control. Since the revival of letters, and still more since the Reformation, the Vatican has been represented in nearly every walk of science, and from Father BOSCOVICH down to Father SECCHI and Father DENZA, whose deaths are comparatively recent, it has helped to widen and deepen the main stream of the world's knowledge by brilliant achievements in inductive research. Why should it make physiology or anthropology an exception to other sciences? Why denounce the application of these to the investigation of social phenomena before their votaries have properly argued out their cases or even made themselves adequately heard? Is it not "on the cards" that, just as the railway and the newspaper have not only lived down

Digitized by Google

Vatican censure but have been pressed into Vatican service, the same reversal of attitude may be witnessed towards medical investigation and even criminal anthropology? The Roman Church contains men of science able to sympathise with every honest attempt to solve nature's problems and to view the "Index Expurgatorius" rather with the eyes of BENEDICT the Fourteenth than with those of some of his less enlightened successors.

IT is now universally recognised that—to use the language of the Lancashire and Cheshire Branch of the British Medical Association—"it is expedient that lying-in women and newly-born infants be protected from the practice of midwifery-nursing by ignorant and untrained persons," and as we have already pointed out there is an almost equally general agreement as to the necessity for bringing all practice by women—not being qualified medical practitioners—among lying-in women, whether as midwives or midwifery-nurses, under some regulation to be prescribed by law. Even Dr. RENTOUL and his followers, as representing the extreme opponents of registration, "are anxious to improve the education of midwifery-nurses and, if need be, to support a practical scheme for their local registration; they do not object to the registration of midwives provided these act as midwifery-nurses *only* under the *immediate* supervision of medical practitioners and are registered as midwifery-nurses only; nor do they object to such proposed legislation as would protect any of the present privileges of *existing* midwives." We may, we hope, consider that the basis of a practical measure has been laid in the agreement expressed by all parties to this discussion. All would seem to be agreed on the following points—that lying-in women and children must be "protected," that the persons whose practice is to be brought under regulation shall be restricted to natural labour, and that any recognition of them shall be such as to make clear that they are in no sense medical practitioners and must assume no medical title. The Midwives Bill, which is practically disposed of for this session, in Clause 12, sub-clause 5, dealing with removal from the Register, enacts that "for the purposes of this section professional misconduct shall, in addition to any other form of misconduct, include any omission to send for a medical practitioner where the case is not one of natural labour." When there is so much agreement all round the natural course seems to be for the different parties to the discussion to come together so as to put down in practical terms what all agree to. To facilitate this, it is well to be explicit as to points which are still the subject of difference. Our object to-day is to note two or three of these. Let us note one between Dr. RENTOUL and the members of the Lancashire and Cheshire Branch. Dr. RENTOUL in his manifesto requires that the midwifery nurses shall act only under the immediate supervision of medical practitioners. The Lancashire and Cheshire Branch of the British Medical Association, however, "are unanimously of opinion that the proposition that it be made compulsory for every woman to have a registered medical practitioner in attendance at confinement, or that no person other than a registered medical practitioner, or a person acting under the direct or personal supervision of such be allowed to attend any case of midwifery, is, however desirable, impracticable." There is, probably, less difference between these views than appears. At any rate, it is obvious that the personal presence of a medical man—overlooking a midwife—at every case is impracticable. If a lying-in woman could afford a double service the need for this legislation would cease. We must be content with a medical practitioner *in reserve*, acting under the proposed Midwives Board, and, perhaps, all things considered, the district medical officer would be the best referee. This is a detail on which there should be no difficulty in coming to an agreement.

There remain two or three other points of prime importance on which there is more difference of opinion. They should be adjusted with a little discussion, but they need more consideration than—even after twenty years—they seem to have received. They have reference to the authorities by which the contemplated Act is to be administered. All are agreed that the chief work to be done shall be done by a board created for the purpose—the Midwives Board. But with regard to the composition of the board there are wide diversities of opinion. The Midwives Bill of the present year gives a board of eighteen—three representatives of the College of Physicians, three of the College of Surgeons, three of the Apothecaries' Society, three of the Incorporated Midwives' Institute, and three appointed by the Lord President of the Council, of whom one at least shall be a woman. The Bill of the Parliamentary Bills Committee of the British Medical Association provides a board consisting of Registered Medical Practitioners to be appointed by the General Medical Council. The Bill of the Lancashire and Cheshire Branch has a Midwives Board of twenty-seven selected from registered medical practitioners to do duty in the following districts:—London and Southern Counties, seven representatives; Birmingham and Midland and Eastern Counties, five representatives; Lancashire, Cheshire, Westmoreland, and Cumberland six representatives; Northumberland, Durham, and Yorkshire, six representatives; and Wales and Counties of West of England, six representatives. Other questions of great importance are—who is to keep the Register? and shall it be national or local? The Midwives Bill assigns the duty to the Midwives Board. But both the Parliamentary Bills Committee and the Lancashire and Cheshire Branch of the British Medical Association require the General Medical Council to keep and publish the Register. According to the former no midwifery nurse is to commence practice in a district without first reporting herself to the medical officer of health. Dr. W. FRASER in his valuable contributions to the settlement of this question in our columns advises local registration, as distinguished from national, on the score of being more proportionate to the humble expenses of training and more effective. There is an equal diversity of views as to the power of removing from the Register for disciplinary purposes. The Midwives Bill assigns this duty to the Midwives Board, but assigns the power of restoration to the Board or to the Privy Council. The Parliamentary Bills Committee gives the power of removing from, and restoring to, the Register to the General Medical Council. The Lancashire and Cheshire Branch proposes that a committee of the Midwives Board shall investigate charges of

Digitized by Google

misconduct and may remove from the Register. Dr. FRASER leaves questions of discipline to the medical officer of health for the town or district, with appeal to the medical officer of health for the county.

A curious difference in the Bills is in the way in which the action of the Privy Council is imported into the administration of the proposed Act. There is an unwise obtrusion of this august body into the Midwives Bill. It has three nominations to the Midwives Board; together with the General Medical Council it has to take steps to secure the first Midwives Board; it fixes a date for the establishment of the Midwives Register with a notice in the *London Gazette;* it must confirm all rules framed by the Midwives Board and approved by the General Medical Council; if the General Medical Council fails it must invite some other suitable body to act or proceed to act itself; and it may direct the restoration of a name to the Midwives Register. In the respective Bills of the Parliamentary Bills Committee and the Lancashire and Cheshire Branch the Privy Council is required to confirm the rules approved by the Board and approved by the General Medical Council. Dr. FRASER proposes that the Local Government Board shall issue directions annually to be observed by midwives as to sanitary conditions in nursing a patient. We have no space left to discuss these various points. But we suggest to all who are in earnest in seeking to protect lying-in women and who do not wish for another twenty years' delay to simplify their suggestions as much as possible. The machinery of any practical measure should be local, inexpensive, and simple. To import the Privy Council into the administration seems to us quite superfluous and hindering Even the General Medical Council is not needed, save in the initiation of the administration to sanction rules. It has repeatedly expressed its willingness to assist so far but no further and has indicated its belief in a local rather than a national administration. The examinations should as far as possible be local and the registers should be local. The realisation of this legislation will be brought about soon or late, according to whether it is kept proportionate to the limited function of the parties to be trained and the limited means of those whose lives are to be saved. Looked at from this side of the question the proposals of Dr. FRASER seem very valuable, and Dr. LOVELL DRAGE, who is opposed to most Midwives Bills, sees in them a solution of the difficulties. Dr. FRASER will do service by still further developing his views as to the machinery for localising examinations and registration. The General Medical Council may be a fit body to govern the medical profession, and yet be unfit for such duties as are involved in the administration of a Midwives Act.

THE DUKE AND DUCHESS OF FIFE AT BRIGHTON.—Their Royal Highnesses the Duke and Duchess of Fife last week visited Brighton, where the Duchess laid the foundation stone of a new wing for the accommodation of the nursing staff of the Brighton Children's Hospital. Twelve bedrooms, with bathrooms, &c., will be provided, and the cost, including furnishing, is put at £1500, of which from £1100 to £1200 is already collected, besides purses to the amount of £179 received by Her Royal Highness.

Annotations.

"Ne quid nimis."

THE LIVERPOOL LADIES' CHARITY AND LYING-IN HOSPITAL.

THE dispute between the board of management and the late medical staff of the Liverpool Ladies' Charity and Lying-in Hospital has been alluded to in several letters by our Liverpool correspondent; but, as the subject is one of importance to the profession in general, we have no hesitation in further referring to it. The charity consists of a hospital containing fifteen beds, attached to which is a staff of three honorary medical officers, a matron-midwife residing in the building, and a staff of nurses. There is also an out-door department for women who wish to be confined in their own homes, much on the same principle as the Royal Maternity Charity of London. The city is mapped out into districts, each with its honorary medical officer and midwives; the former is sent for in cases involving difficulty. At the hospital the board of management objected to the normal cases coming under the supervision of the medical officer on duty, and insisted on the matron-midwife admitting all patients and having charge of them during their confinements unless she detected anything abnormal, in which case she had orders to summon the medical officer on duty. The late staff objected to this practice, and demanded that all patients in the hospital should come under their supervision; and further that the matron-midwife should act under their direction, similarly to a house surgeon obeying the orders of his chief. A meeting of the subscribers was summoned to place before them the matter in dispute, with the result that a resolution was carried apparently giving charge of all patients to the medical staff, but in reality confirming the attitude of the board of management towards the medical staff. The staff then came to the conclusion that, as their proper position in the hospital was denied to them, they could not retain office any longer and forthwith resigned in a body. Consequently on their resignation the board of management advertised for two honorary hospital medical officers and for several district medical officers to fill the vacant posts; the 18th inst. was fixed as the latest date for receiving applications from intending candidates. The result must have been as humiliating to the board of management as it is satisfactory and creditable to the local members of the profession. No application was forthcoming. Not one member of the profession was found to be desirous of being connected with an institution which showed so little regard for the feelings of its medical staff. Our correspondent alluded to a meeting of the local members of the profession which took place on the 11th inst., to protest against and to denounce the unreasonable conduct of the managers of this charity towards its medical staff. The meeting, at which 215 gentlemen and two ladies were present, was unanimous, and carried two resolutions, the latter of which advised the local members of the profession to have nothing to do with a charity which was capable of acting thus to its medical staff. Mr. Mitchell Banks in an able speech said that he trusted that no medical man would demean himself by applying for a post of such questionable dignity. The result of this meeting has been all that was to be desired, and an object-lesson has certainly been given to the board. We will not dwell on the abuse which has been poured on the heads of the staff of the hospital and on the profession in general in letters addressed to the local papers; this is a subject beneath notice. It is amusing, however, to find the ignorance displayed by some of the

Digitized by Google

writers in their charges of inhumanity against the "doctors." One gentleman in alluding to the use of the pelvimeter by a member of the staff declared that it was a barbarous practice. We wonder if he is under the impression that it is used for vivisecting purposes. All the troubles at this charity might have been averted if the medical staff had been represented on the board of management. We trust that in future the members of this board will confine themselves to the ordinary duties of hospital management, and cease to encroach on matters which they do not understand.

THE BIRTHDAY HONOURS

WHILE sincerely congratulating the members of the medical services—for the name of no civilian member of the medical profession occurs in the list—who are recipients of any honours and distinctions, we can only express our regretful surprise at the extremely limited number of the members of our profession who have been deemed worthy of being included in the brithday list. Brigade-Surgeon-Lieutenant-Colonel Alfred Swaine Lethbridge is promoted to be a Knight Commander of the Order of the Star of India, Brigade-Surgeon-Lieutenant-Colonel Benjamin Franklin to be a Companion of the Order of the Indian Empire, Dr. J. Rogers Pasha to be a Companion of the Order of St. Michael and St. George, and Surgeon-Major-General Charles Dodgson Madden to be a Companion of the Order of the Bath.

MEDICAL CERTIFICATES AND BOARD SCHOOLS.

WE have frequently discussed the conduct of the London School Board with regard to medical certificates, and we have now to comment upon the same subject as it appears at Macclesfield. At the recent monthly meeting of the Macclesfield School Board the Rev. Father Robinson, who was in the chair, proposed the following resolution :—

"That, with a view to secure the more regular attendance of children at school on the one hand, and to avoid unnecessary prosecution of parents on the other, a medical officer be appointed, whose duty it shall be to examine all children sent to him by the clerk and to report as to their fitness or otherwise to attend school; and that the clerk keep a counterfoil record of children so sent; and that the medical officer be paid half-yearly at the rate of 1*s.* for each child so sent."

In the course of his remarks he is reported by the *Macclesfield Courier* as saying "that by appointing a medical officer they would be taking upon themselves the onus of paying for what they had a right to do by law." We must inform Father Robinson that, if he is rightly reported, and if he means that a School Board has a right to demand a medical certificate, he is wrong. A School Board has no more right to demand a medical certificate than it has to demand a certificate of baptism. Father Robinson's resolution is an attempt to grapple with a difficult question, but we do not quite see how it is going to work, and it is open to the same objection as the resolution of the London School Board. If the Board gets answers to its advertisement we suppose it will appoint a medical man, but we doubt if any will apply with the prospect of having to run all over Macclesfield and examine cases at 1*s.* a head. No parent would bring his child to the medical officer, for he would naturally think, "If he is too ill to go to school he is too ill to go to the medical man." Of course in many cases this reasoning would be wrong, but still it would certainly be used. All the old stories about incorrect certificates were brought up by Mr. Brown and Mr. Hammond. That certificates are often given by those who have no right to give them—e.g., herbalists, &c.—we can well believe, but that incorrect certificates are granted by qualified men we do not believe, except in a very few cases. We cannot see why the Board should not be satisfied that any medical man should sign certificates. In case of any doubt arising the School Board medical officer might be at liberty to examine into the case *in consultation* with the original giver of the certificate. We think that no general practitioner would object to this, for something analogous is constantly being done by insurance offices, &c. But the procedure of the London School Board, as it stands in the resolution of May 30th, 1895, is intolerable, and the Macclesfield board, by proposing to make the clerk the judge, is scarcely acting more wisely. The fee of 1*s.*, too, is absurd. However, we await the development of the scheme with interest and shall have more to say upon the matter.

THE "NEW STREET DANGER" AGAIN.

A SOMEWHAT alarming phenomenon manifested itself in Northumberland-avenue on Monday morning last. About ten o'clock dense volumes of black smoke were observed to be issuing from several culverts in the road extending for a considerable distance immediately in front of the Victoria and Métropole Hotels. The character of the smoke and its smell could leave little doubt as to what the origin of the subterranean fire could be. It was just that which might be expected on the burning in a confined space of the bituminous cement or gutta-percha used for electric lighting cables. For some cause or other the mains had become over-heated. Shortly after the occurrence the electric light at THE LANCET offices was found to be turned off—a fact which confirmed the view of electric mains being the source of the mischief. Luckily in this instance there did not appear to be any leakage of coal gas, otherwise the result might have been very serious. The fire, however, was soon subdued by the fire brigade pouring water down the culverts. The incident will of course be inquired into, and the proceedings should possess some interest in throwing, perhaps, some light on the question as to whether the electric mains *per se* could cause an explosion.

SHORTHAND FOR MEDICAL STUDENTS: PETITION TO THE GENERAL MEDICAL COUNCIL.

A PETITION signed by nearly two hundred members of the Society of Medical Phonographers, to which is appended the names of many prominent members of the medical profession, including Sir Joseph Lister, President of the Royal Society, Dr. Wilks President of the Royal College of Physicians of London, and Mr. Christopher Heath, President of the Royal College of Surgeons of England, has been presented to the General Medical Council and will, we presume, be considered at the approaching meeting of that body. The prayer of the petitioners is that shorthand should be an extra optional subject for the Preliminary Examination required by the General Medical Council, and in view of the great saving of time and labour and the facilities which a knowledge of shorthand gives to its possessor in recording clinical and scientific observations we have no doubt that the Council will carefully consider the prayer of the petitioners. The use of shorthand in education is becoming daily more and more recognised and especially so in the case of the learned professions. Its advantage to the legal profession is obvious and the clerical profession has been greatly indebted to it. As the petitioners state, the value of shorthand to staff officers of the army has lately been recognised in the Queen's regulations and has been made compulsory for Foreign Office *attachés*. In the medical profession its increasing use is reflected in the growth of the Society of Medical Phonographers, inaugurated a little more than a year ago, which has increased from sixty to two hundred and forty members, some of them with an experience of from thirty to forty years, and representing every branch of the profession. Provided a

Digitized by Google

knowledge of shorthand is acquired before the student commences his medical studies and also that he has learned the proper method of using it which he may do by the perusal of an excellent little book [1] written by Dr. Gowers and published by the Society of Medical Phonographers the embryo practitioner is armed with an instrument which should greatly assist him in his studies. Should, however, the General Medical Council recognise shorthand as an optional subject at the preliminary examination it would be wiser not to limit the system to Phonography, excellent though that system may be; indeed, arguments might be advanced against the official recognition of any one particular system. Phonography is perhaps one of the best for scientific work, but it is certainly not perfect from a practical point of view. To officially recognise one system would not be fair to the others.

COPPERED PEAS.

AN important decision was given last week on the greening and preserving of peas with copper. It appears that a conviction was obtained against a wholesale provision dealer in the Borough for selling preserved peas containing 3·16 grains of sulphate of copper, which the magistrate held to be an ingredient in sufficient quantity to be dangerous to health. There was some difficulty in giving judgment in the appeal as the opinions of authorities were greatly at variance on the question of the quantity that should be permitted. In the present case, however, it was considerably in excess of the limits which most authorities had laid down. We should like to see the use of copper salt for this purpose interdicted altogether or else only allowed when the vendor agrees to label in distinct and moderately large characters the tin or packet containing them to the following effect: "These peas are coppered." That some distinct legislation is wanted on this subject is evident from the statement that the annual consumption of these peas in England is estimated at 20,000,000 tins. Assuming, therefore, that each tin contained the quantity of sulphate of copper stated to be present in the sample in the present case this would amount to 9000 lb., or over 4 tons, of sulphate of copper taken with this form of food annually into the human system; and who shall say that this quantity of copper is so uniformly distributed that one consumer does not get more than a three-grain dose from time to time?

THE CRIMINALITY OF THE FRENCHWOMAN.

THE statistics of crime are in France, as in other countries, several years in arrears. It is not surprising, therefore, that those relating to the year 1893 should have been published only last week. Criminologists may be interested to know what part the Frenchwoman takes in offences against the established rules of civilised society. Of 4269 accused persons in 1893 3673 were males and 596 females—a proportion of 6 to 1. In other words, woman was responsible for 14 per cent. of the crimes committed, a diminution since the period comprised between the years 1871–76, when the percentage was 17. As might be expected, offences against persons predominate over those against property, being 19 per cent. in 1876–80, 18 per cent. in 1881–85, 21 per cent. in 1886–90, 20 per cent. in 1892, and 17 per cent. in 1893. Offences against property rights have progressively descended from 13 per cent. in 1876–80 and 12 per cent. in 1892 to 11 per cent. in 1893. Prosecutions for infanticide have likewise decreased in the following proportions: 1889, 210; 1890, 174; 1891, 148; 1892, 154; 1893, 132; the annual average for 1876–80 having been 207. We may conclude that the criminal instincts of our Gallic sisters are comparatively feeble, and that what appears to the justice-loving Briton as culpable indulgence on the part of French juries *vis-à-vis* of the erring woman, more especially in what our sentimental neighbours denominate *drames passionnels*, has not had the effect of encouraging the weaker sex in wrong-doing. Alphonse Karr has, in one of his books, cynically defined woman as *un être qui s'habille, babille, et se déshabille* (a being who dresses, chatters, and undresses). A short sojourn in this giddy city of pleasure will lead to a like conclusion in so far as a large proportion of Parisiennes is concerned. The absorption of their time in the above-named important occupations may, perhaps, account for the rarity of their appearance in criminal records and also for the predominance of male crime.

[1] The Use of Shorthand by the Student.

QUESTIONABLE TASTE.

THE Metropolitan Hospital Sunday Fund has issued a notice (which we publish elsewhere) expressing disapproval of street collections on Hospital Sunday, and we almost wish it were possible to withhold the benefits of the Fund from those hospitals who make Sunday hideous by organising street processions in aid of their respective charities. On Sunday last in a certain part of London there was a street procession organised in aid of a hospital which for the present shall be nameless, as we do not know whether the hospital authorities were responsible for it or whether the tradesmen who took part in it and thus secured a big advertisement for themselves were responsible. In addition to the usual bands and banners of friendly societies which accompany these processions there were tradesmen's carts, decorated with flowers and vegetables, the name of the owner of the vehicle being, of course, conspicuously visible. To this there can, perhaps, be no serious objection, though we question the taste of the proceeding; but the principal "attraction" was a man on what was supposed to be a sick bed, and attended by two nurses, one of whom, we understand, was a qualified nurse attached to a local mission and the other a person masquerading in a nurse's costume. Comment is needless.

THE POOR-LAW SCHOOLS COMMITTEE: SEVERE CRITICISM.

THE Poor-law Schools Committee and its report have not been permitted to go free in the matter of criticism—and criticism, moreover, of a severe character. The London and District Poor-law Officers' Association have recently held a meeting in London at which the report in question was handled by several of the members in no friendly manner. The principal speaker was Mr. H. D. Aslett, superintendent of the branch schools of the Kensington and Chelsea school district, and in a lengthy paper he traversed the assertions made in the report in many directions. Not alone with the substance of the document was he at variance, but he criticised the constitution of the Committee and the selection of witnesses as well as many of the statements of particular witnesses. The general tenor of his paper may be gathered from the terms of the resolution which he submitted to the meeting, and which ran:—

"That in the opinion of this association the report of the Committee on Poor-law Schools gives evidence of bias; too much has been made of individual cases of admitted failure, to the exclusion of thousands and thousands of satisfactory ones; the weakest condition of the weakest school is the measure with which all are meted; the description of the schools much more appertains to what they possibly were twenty or thirty years ago; and the report does not recognise the forward strides made in all the schools during the past ten years."

He felt that too much had been made of the alleged evils of aggregating children in schools, and pointed out that, whilst many schools were for comparatively small numbers of inmates, even the large schools were divisible into

Digitized by Google

three sections—boys, girls, and infants—having little in common. He regarded ophthalmia as potent for mischief in other places equally with Poor-law schools, and did not regard the disease as by any means a necessary corollary to the school system. With reference to the physical condition of the inmates of the schools, he looked upon the bad record as arising from a natural selection of the unfittest for these institutions. The degree of faith to be placed in the much-lauded boarding-out system seemed to him to be smaller than is generally felt to be the case, having in view the statistics placed before the Committee by those most favourable to it; and, in his opinion, the standard of excellence in matters educational is quite as high in Poor-law schools as in most of the elementary schools in the country. Others who spoke felt it to be hard that no more praise had been accorded to the painstaking work of the Poor-law guardians and officials to better the system as at present existing. The meeting at the end of this discussion unanimously passed the following resolution:—

"That in the opinion of this meeting of this association the report of the Poor-law schools is unsatisfactory, unjust, and unfair to metropolitan schools generally, which can show very satisfactory results, as an impartial inquiry must prove; and this meeting suggests to the National Council that some action shall be taken in the matter."

THE SURGICAL TREATMENT OF INTRACRANIAL TUMOURS.

IN a paper in the last number of the *American Journal of the Medical Sciences* Dr. Stieglitz, Dr. Gerster, and Dr. Lilienthal describe three cases in which operation was performed for intracranial tumour. In one case the patient recovered and did well for at least a year after operation; in the other two cases death followed operation. The first patient was a woman aged twenty-five, who, in October, 1891, while talking to her husband, suddenly felt the thumb and forefinger of her right hand twitch. The spasm gradually spread up the arm to the shoulder and face, leading to a general convulsion, with loss of consciousness. Several attacks similar in character followed, and in February, 1892, there was definite paresis of the right hand, which gradually became more marked in the course of the next few weeks. There was no headache, sickness, or optic neuritis, and anti-syphilitic treatment failed to influence the symptoms. It was concluded that a tumour was probably present in the left anterior central convolution near the junction of the middle and lower thirds. Operation was performed on June 25th, 1892, and a sub-cortical cystic tumour was found in the position indicated above and an ounce of straw-coloured fluid escaped. The cyst-wall was perfectly smooth, but it was considered inadvisable to attempt the removal of this. The patient made a good recovery and by the end of the following October she was able to write and sew, a marked difference from her condition before operation, when she had been unable to use the hand at all. In December, however—that is, six months after operation—she had a general epileptic seizure which began in the right arm, and she continued to have twitchings on the right side with subsequent weakness of the limbs on the affected side. No other symptoms were superadded until March, 1895, when she began to suffer from severe headache, and at this date, for the first time, the optic discs were found to be cloudy and slightly swollen. It was thought that there had been a recurrence, or rather an extension, of the growth in the cyst wall, and at the operation a small maroon-coloured mass was found towards the upper margin of the opening in the skull. This was found to be conical in shape, with the base at the surface and the apex deep in the brain substance. It was sarcomatous, and islets of growth were found in the surrounding brain substance. There was temporary interference with speech after the operation, but this soon passed off and power began to return in the paralysed limbs. A year after this second operation the condition of the patient was very satisfactory. There had been no recurrence of the severe seizures or even of the slight twitchings, and there had been considerable return of power in the paralysed arm, the thumb and index finger alone remaining powerless. Cutaneous sensibility is said to have been perfect, but there was considerable interference with the muscular sense in the hand. The second case was that of a Russian aged thirty-three, who came on account of loss of vision, and was found to have intense optic neuritis. There were also severe headache, staggering gait with tendency to fall to the right, slight weakness of the right side of the face, and some indefinite limitation of the movements of the right eye. Total deafness on the right side and partial reaction of degeneration in the facial muscles of the right side were moreover present. Trephining was done in the right occipital region as it was supposed the tumour was situated in the ventro-cephalic part of the right cerebellar lobe close to the internal auditory meatus. The intracranial pressure was found to be enormously increased and the tentorium was pressed up from below. The tumour could not be reached, and so enormous was the intracranial pressure that there was a large hernia cerebri which had to be removed. The wound subsequently became septic and the patient died a fortnight after the operation. At the necropsy a glio-sarcoma the size of a small apricot was found, involving the anterior half of the right cerebellar hemisphere and indenting the same side of the pons. The third case was that of another Russian fifty years of age who suffered from right-sided fits and subsequently from headache and disturbance of speech. There was also weakness of the right arm and right side of the face, but no optic neuritis until more than eight months after the first fit. Operation was carried out, but the patient succumbed to the shock and loss of blood. A large tumour was found in the left Rolandic area. These three cases furnish examples of the difficulties to be met with in dealing surgically with intracranial tumours. The last two show that trephining alone, even when the tumour is not removed, has certain dangers. Those arising from the enormously increased intracranial pressure and consequent protrusion of the cranial contents after trephining in the case of sub-tentorial tumours are strikingly illustrated in the second case.

LONDON DUST.

ONE of the unpleasant effects of the recent spell of dry weather in London has been the unusually large amount of dust that has been flying about. The irritation of the mucous membranes of the respiratory tract and conjunctivæ which it produces is no doubt responsible for many of the nasal and bronchial catarrhs which are apt to occur at this period of the year, especially in those who are predisposed to them, and, besides this simple irritative effect, a large amount of organic matter is naturally inhaled. Dust is chiefly made up of mineral particles to which is added a variable amount of organic matter arising from the decomposition of animal and vegetable refuse, and we may feel quite sure that the dust of overcrowded London contains a large share of the latter. It is impossible to estimate with any degree of exactitude what detrimental effect on the general health a period of dusty weather may have, but we are forced to think it must have some when we look at the disastrous results to health which continuous inhalation of particles causes. So in a minor degree is the dust of the streets injurious, not perhaps to any practical amount to those who are healthy, but to those already suffering from pulmonary complaints it must necessarily be

Digitized by Google

harmful from the irritation and coughing which its inhalation causes. It is possible that a time will come when most of the traffic of the streets will be carried on by means of autocars and bicycles, in which case the decrease in the number of horses would be accompanied by a decrease in the amount of dust and especially of the organic matter which now so freely enters into its composition.

THE ILLNESS OF SIR J. RUSSELL REYNOLDS.

WE deeply regret to be unable to speak hopefully of Sir J. Russell Reynolds's condition. The complete prostration still remains, and although no new symptoms have appeared his state is one that still gives rise to the deepest anxiety. The breathing has been easier since the appearance of our last report, but the fact that during the week that has elapsed no improvement of the terrible weakness has taken place prevents us from speaking to our readers in any optimistic manner. We may hope for the best, but it would be wrong not to be prepared for the worst. By the command of the Queen Sir James Reid has visited Grosvenor-street several times, and the condition of the patient is daily reported to Her Majesty. The numerous personal inquiries and messages of deep sympathy that have been received by his family from sources far and wide bear touching testimony to the affection and esteem in which Sir John Russell Reynolds is held by all who know him.

RECURRENT PARALYSIS OF THE THIRD NERVE.

IN a recent number of the *Wiener Klinische Wochenschrift* Dr. Karplus has a paper on this subject, in which he relates two interesting examples of it, in one of which examination post mortem was possible. An abstract of this paper appears in the last number of the *Neurologisches Centralblatt*. The first case was that of a woman, thirty-seven years of age, without any history of nervous disease in her family. She had suffered from her eighth year from attacks which she herself associated with a severe injury. The attacks consisted in sudden and severe right-sided headaches which came on without warning. A few years after their commencement ptosis appeared and the duration of the whole attack extended over five or six days. The attacks became more and more frequent, and at the time at which she was seen they came on every three months. For the previous six months also recovery from the paralysis of the third nerve had not been complete. During three pregnancies the patient had never had an attack. Examination during an attack showed complete paralysis of all branches of the third nerve. On the temporal bone just under the zygoma on the right side there was a point tender to pressure. Sensibility in the region of the second and third branches of the trigeminal nerve was otherwise normal, while during the attack hypo-æsthesia and hypo-algesia were present in the region of distribution of the frontal branch of the fifth nerve. The second patient was a man aged forty-three, who was admitted to the hospital on account of progressive paralysis. The history was that at the age of six months he had had an attack of sickness, with subsequent ptosis, which passed off in a few days. After that until he was twenty he had similar attacks every two or three weeks, accompanied with severe right-sided headache. After his twentieth year recovery from the ptosis had been incomplete and he had begun to squint. On admission he had a dilated, inactive pupil on the right side, divergent strabismus of this eye, and ptosis. He had, under observation, every three or four weeks attacks of complete paralysis of the third nerve with severe headache and sickness. The fundi were normal. The patient died after a succession of epileptiform attacks. At the necropsy a tumour the size of half a pea was found in the third nerve and connected with the dura mater. This was found to be a neuro-fibroma which involved the third nerve on all sides. The fibres of the nerve were degenerated, but the cells of the nucleus were unaltered, although the supporting tissue was less abundant on the right side than the left. Dr. Karplus regards the tumour as having been probably congenital, and by reason of its presence and pressure to have led to degeneration of the nerve fibres. From his observations he is inclined to regard these cases of recurrent palsy of the third nerve as the result of changes at the base of the brain. The affection of the branches of the trigeminus on such a hypothesis is intelligible, and he does not accept the view that circulatory disturbance is an efficient cause of the conditions.

THE FOUNDATION OF A JENNER MEMORIAL MEDAL.

IN another column will be found a letter signed by the officers of the Epidemiological Society in which it is stated that the Society proposes to found a medal in honour of Jenner, to be awarded to persons who shall have added to the knowledge of epidemiology and preventive medicine. We note this intention with much pleasure—in the first place because we are satisfied that the profession will be glad of this opportunity of founding a memorial to Jenner on the centenary of his great discovery, and, secondly, because the Epidemiological Society is peculiarly fitted on account of its association with the subject of vaccination to undertake the task.

ANALYSES OF DIPHTHERIA ANTITOXIN.

THE weekly bulletin of the State Board of Health of Massachusetts for the week ended April 4th contains some valuable results as to the quantitative analysis of the diphtheria antitoxins offered for sale in that State. In the case of the serum of Behring (No. 2), of that of Parke, Davis, and Co., and of Mulford and Co. the antitoxin was up to the advertised strength. In the case, however, of the serum of the Pasteur Institute of Paris (Roux) it was found that the ten cubic centimetres of serum which were tested contained a total of 500 antitoxic units instead of 600 units; while in the case of Gibier's diphtheria antitoxin, New York, it was discovered that a bottle professing to contain 2500 units contained from 625 to 750 units only. Results such as these are obviously of considerable importance and are calculated to very materially vitiate statistics relative to dosage.

AN UNQUALIFIED DRUGGIST.

SOME remarkable disclosures with reference to a druggist's business were made in recent legal proceedings. The defendant—a druggist—was sued for £25, which was the balance of a sum for which he had bought the business. The defendant did not deny that the sum was owing, but he pleaded that in selling the business the plaintiff had misrepresented things to him, and on that score he put in a counter claim for £50. The evidence went to show that the plaintiff was an unqualified druggist, and it was further alleged that the large profits he had made were due to an extensive sale to females of a mixture for illegal purposes and that the defendant, as he did not continue to sell this mixture, found the profits far below what he had been led to expect. In the end, after conflicting evidence, the plaintiff got his £25 and the defendant was awarded the same sum on account of the fraudulent misrepresentation, but without costs to either side. This case is one of those which show that in all probability a large trade is often done in these illegal sales of medicines, and in this case the vendor in some measure guarded himself by not allowing his name to appear on the bottles. The composition of the mixture was not given, but it was said to be a very

Digitized by Google

dangerous one and a combination of drugs which no qualified man would use. The greatest vigilance is necessary to control the sale of medicines for illegal purposes, and exemplary punishments should be passed on those who are convicted.

THE GENERAL MEDICAL COUNCIL.

THE Queen has nominated Mr. Thomas Pridgin Teale, M.B. Oxon., F.R.C.S. Eng., to be again, for the term of five years from the 23rd inst., a member of the General Council of Medical Education and Registration of the United Kingdom. This is Mr. Teale's fifth period of service. His interest in education, medical and otherwise, is well known. At the last meeting of the Council he gave notice of a resolution on the subject of excessive examinations which is sure to raise some very important questions.

THE MEDICAL SOCIETY'S CONVERSAZIONE.

THE annual conversazione of the Medical Society of London took place on May 18th, when a large and distinguished gathering of Fellows and visitors assembled to hear the annual oration, which was delivered by Dr. W. H. Allchin. The subject chosen was "The Breaking Strain," and the address will be found in full in another part of our present issue. The attention with which its delivery was received and the enthusiasm with which the after-vote of thanks was accorded to the orator could not fail to demonstrate to Dr. Allchin how much his venture into the fields of the transcendental had been appreciated. The presidential reception which was held afterwards was largely attended and the newly decorated and attractive rooms of the society were crowded until a late hour.

RECENT PAUPER STATISTICS.

THE monthly comparative statements of pauperism issued by the Local Government Board have now for some time been so unsatisfactory that it is pleasing to have to record of the latest—in respect of February last—that some material improvement is manifest. Having regard to the whole of England and Wales, as divided by the Registrar-General into eleven divisions, it is satisfactory to note that with a single exception (the north midland group of counties, and that only in respect of one week) there was in February last, as compared with 1895, a decrease in pauperism in every division. Not alone so, but in London the improvement ranged from 18·9 to 28·2 per cent. in the several weeks of the month. In the country as a whole the decreases were 7·1 per cent. in the first week, and in the remaining weeks 10·8, 12·5, and 10·7 respectively. It may be that these data are more satisfactory on paper than in actual fact, inasmuch as February of the present year was free from the heavy frost which prevailed in that month in 1895. But none the less the returns are far from displeasing in the face of previous statements.

THE THYROID TREATMENT OF MYXŒDEMA AND CRETINISM.

THE efficacy of this mode of treatment now stands in need of no proof. So many illustrations have been published showing at a glance the condition of the same patient before and after administration of thyroid extract that the subject is in some danger of becoming stale and tiresome. But there are many clinical observations which can be made on patients during the early period of treatment which are of interest and importance. In the last volume of the Edinburgh Hospital Reports there is a very interesting paper by Dr. Byrom Bramwell which contains his observations on twenty-three cases. Dr. Bramwell has had experience of all the forms of administration, subcutaneous injection, the raw gland itself, the fluid extract, and the dried extract. He prefers the latter and confirms the statement of others that its activity does not appear to be impaired by keeping. An interesting clinical observation is that patients suffering from myxœdema and sporadic cretinism seem to be much more susceptible to the action of thyroid extract than those suffering from some skin diseases. "In most cases of myxœdema unpleasant symptoms and acute thyroidism are apt to be produced if the dose exceeds four tabloids daily (quarter of sheep's thyroid gland), but in several cases of psoriasis and ichthyosis I have given twenty, thirty, forty, and in one case even seventy-four tabloids (equal to one, two or even five average sheep's thyroids) per diem." In several cases there was an increase of mucus and uric acid in the urine when treatment was commenced. In one case this was extremely marked, the deposit of mucus in the specimen-glass looking like a large coagulum. Dr. Bramwell calls attention to the great differences in susceptibility met with in different people, and urges the necessity of caution and of giving small doses at the commencement of treatment. The danger of syncope is referred to. Death has occurred from this cause in a case in which the myxœdema was rapidly subsiding, and it is recommended that when the thyroid extract is very rapid in its effects cardiac tonics and stimulants should be given at the same time. The paper is written in Dr. Byrom Bramwell's usual clear style, and, as in all his papers, the illustrations are both useful and truthful.

THE LANCET AND THE HYDERABAD COMMISSIONS ON CHLOROFORM.

WE are pleased to be able to announce that we have reprinted in book form the Report of THE LANCET Commission appointed to investigate the subject of the Administration of Chloroform and other Anæsthetics from a Clinical Standpoint, together with the Reports of the First and Second Hyderabad Chloroform Commissions. The volume consists of nearly two hundred pages. In reproducing the Reports some slight changes have been made in the text of the introduction and elsewhere, these having been necessitated by the character of the original Report, which, as it appeared serially in our columns, needed textual reconstruction to render it consecutive; and a full description of the Manometer Experiments has (by the kind permission of the Nizam and the Government of Hyderabad) been added. We venture to hope that the work will prove useful to the profession as a record both of experimental investigations and of clinical research with regard to a subject of the highest importance to mankind. Further particulars concerning the publication will be found in our advertisement columns.

THE MEDICAL OFFICER OF HEALTH OF THE WEST RIDING OF YORKSHIRE.

THE West Riding County Council last week appointed as their medical officer of health Dr. James Robert Kaye, a gentleman of large experience in sanitary administration who has for upwards of six years been medical officer of health of Huddersfield and medical superintendent of the infectious hospitals of that populous borough. He has for some years displayed both zeal and ability in directing public attention in his district to the necessity of sanitary improvements and in demonstrating the advantages—moral, physical, and material—which result from an intelligent and consistent observance of the laws of hygiene. Such persistent but judicious advocacy of a high standard of sanitary efficiency is a praiseworthy characteristic of a public official and does much to counteract the prevalent apathy of local authorities. Dr. Kaye is a native of Perthshire and studied medicine in St. Andrews and Glasgow. In addition to his medical degrees obtained at Glasgow University in

Digitized by Google

1880 he holds the Diploma of Public Health of Cambridge University and is a Fellow of the Chemical Society of London.

ONE OF THE LAST OF THE CHARTIST PRISONERS.

THE Rev. Arthur O'Neill, who died at Birmingham on May 14th, was born at Chelmsford in 1819, and in 1835 commenced the study of medicine in Glasgow University, but soon abandoned medicine for divinity. He also joined the Chartist movement, and in 1842 was charged with sedition and imprisoned in Stafford Gaol for nearly twelve months. He was for more than forty years pastor of a Baptist chapel in Birmingham. There is probably now only one survivor of the Chartist prisoners.

THE Council of the Hospital Sunday Fund ask us to state that they do not give their sanction to, or approve of, boxes being carried about the streets soliciting donations in aid of this Fund. The proper places for making collections are the several places of public worship, to which payments by those unable to attend may be sent. Payments may also be made directly to the Lord Mayor, who is the treasurer of the Fund, at the Mansion House. The collection will take place this year on Sunday, June 14th.

THE committee of the Howard Association have adopted a resolution to the effect that the clauses in the Education Bill concerning pauper children do not contain sufficient safeguards against the abuse of the boarding-out system. We earnestly hope that if the clause in question is as inadequate as the resolution of the Howard Association seems to imply measures will be taken in committee to meet the deficiency.

WE have received a copy of a leaflet issued by a body called the Church Anti-vivisection League. It accuses the Clergy of subsidising vivisection and of alienating the laity. It also begs the clergy not to give any offertory to a hospital that "has a vivisectional laboratory attached." We hope to return to this subject next week.

THE Colonial Office has been informed by telegram from the Governor of Hong-Kong that seventy fresh cases of bubonic plague occurred in the colony in the week ending May 19th, and that the number of deaths from the plague in the same period was ninety-one.

THE QUEEN has been pleased to sanction the following appointments to the Order of the Hospital of St. John of Jerusalem in England. To be Knights of Grace: Sir Wm. MacCormac, F.R.C.S. Eng., and Mr. Samuel Osborn, F.R.C.S. Eng.

THE EMPEROR FRANCIS JOSEPH has conferred the honorary degree of Doctor of Medicine on Sir Joseph Lister, President of the Royal Society, on the occasion of the celebration of the Hungarian Millennium.

MADAME ADELINA PATTI has arranged to give another grand morning concert at Swansea in aid of the Swansea Hospital and the poor of the district round Craig-y-Nos. The date fixed is Aug. 6th.

THE Sanitary Institute have accepted an invitation from the city and county of Newcastle-upon-Tyne to hold a sanitary congress and health exhibition in that city in the autumn of this year.

THE festival dinner at the Imperial Institute on June 10th in aid of the re-endowment of Guy's Hospital, at which the Prince of Wales is to preside, will be followed by a reception.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XX.

The First Public Meeting of Members of the Royal College of Surgeons of England.—Mr. Lawrence's Speech from the Chair.—The Condemnatory Resolutions.—Wakley's Amendment.—Successful Oratory.

ON Saturday, Feb. 18th, 1826, the first public meeting of Members of the Royal College of Surgeons of England was held at the Freemasons' Tavern. For the first twenty years following the granting of the Charter there had been open dissatisfaction amongst the Members, who, be it remembered, comprised the flower of the general practitioners of England. Until 1815 it was not necessary for a medical man to hold any qualifications whatever. No government licence, no diploma from a state-supported or state-recognised body was necessary, and, *a fortiori*, no university degree. Therefore a large proportion of the medical men in the country were what nowadays would be termed "unqualified." They possessed qualifications to practise, certainly—for example, they had generally served several years of apprenticeship to men grown grey in the pursuit of the healing art, and they were mostly sound obstetricians, expert prescribers, and accurate dispensers; but of all standing derived from the successful endurance of the tests of examination they were guiltless. This was the plight of many of the English practitioners before 1815; and even after that date, inasmuch as the Apothecaries Act was not a retrospective one, there were as many unqualified as qualified practitioners in the country. But those who were qualified had generally received their diploma from the Royal College of Surgeons of England and represented the flower of their order—the men who had gone through a recognised training at a general hospital and had satisfied independent examiners that they had made good use of their time while walking the wards.

It must be remembered that these men were in many cases actually the same individuals who had prevented the old Corporation from obtaining at the hands of Parliament a legalisation of its Acts and a consequent re-establishment by their well-timed request to Lord Thurlow to come to their assistance. It was the outcome of their decided and united action that the House of Lords had been put upon its guard against the schemes of a few interested members of the Court of Assistants and had in 1797 refused to pass a bill sanctioning the re-constitution of the old Barber-Surgeon Company while all the abuses that had crept into it during its centuries of somewhat precarious and ill-established existence made an integral part and an important parcel of its programme for a new life. These rightly recalcitrant Members had observed with pleasure the dissection by the great Lord Thurlow of the plans of their would-be masters and the consequent rejection of the same by the country. When, therefore, the Court of Assistants received three years later from King George III. a royal charter giving them in addition to a dignified position all the unwarrantable rights for themselves that they had previously unsuccessfully demanded from Parliament, the wronged Members knew all the arguments against the granting of the charter by heart. Yet although they were disaffected,

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., and XIX. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, May 2nd, and 16th respectively.

Digitized by Google

and rightly, they made no common cause. Their leaders, who were their opponents, had received royal recognition and the fight seemed over. If there had been an outspoken and liberal medical paper in 1800 the Council and officers of the new Royal College would not have enjoyed the peaceful time that they did, but the help that could have been lent to the cause of justice by a strong editor was not then forthcoming. The only medical paper existent at the time speaking with any sort of authority was Dr. Roderick Macleod's decent but somewhat inept monthly publication *The Medical and Physical Journal*, and the proclivities of this journal were strongly aristocratic. So that Saturday, Feb. 18th, 1826, was an important day for the reforming spirits of the College, for it was on that day that the first organised step was taken by the Members against their leaders.

Mr. William Lawrence was in the chair on the occasion and was supported by Mr. Tyrrell of St. Thomas's Hospital, whose close relationship with Sir Astley Cooper did not prevent him from realising which side was right. There were 1200 persons present, but a certain proportion, probably a quarter, of these were not Members of the College, but only individuals of the general public interested in one or other side of a quarrel the merits of which had been widely discussed owing to Wakley's direct and uncompromising methods of comment in THE LANCET.

Mr. Lawrence (to whom a more lengthened reference will soon be made) in an eloquent opening speech constituted himself the mouthpiece of the aggrieved Members. All the points that had been insisted upon by Wakley and Mr. James Wardrop—under the pseudonym of "Brutus"—in THE LANCET were introduced into Mr. Lawrence's speech He dwelt upon the cruel and ridiculous disabilities of the Members in almost the words that were used in THE LANCET and picked to pieces in the most laughable manner the by-law precluding all but a few teachers in London, Dublin, and three Scotch towns from giving certificates of attendance upon scientific lectures. Its obvious grammatical frailty came in for notice no less than its cruelty to the students and its evidences of greed. Mr. Lawrence, fastening upon the words "to promote sound chirurgical knowledge,"[2] said it would seem that sound knowledge was the sort acquired in the winter, when the hospital lecturers were delivering their courses, while unsound knowledge was liable to be imparted in the summer, when only the excommunicated schools of the Graingers and Brookes were able to give the student the assistance and facilities for practical work that he required. After a detailed comparison of the merits of the hospital surgeon with those of the men who were now prevented from officially teaching, in the course of which he incidentally mentioned that under the College's present restrictive edict the famous school of William Hunter could not have existed, Mr. Lawrence went on to point out that the privilege of recognition must have been conceded to Scotland in some mockery, for it was well known that the schools of Aberdeen and Glasgow possessed no facilities for obtaining subjects, so that they could not give the instruction that the college had licensed them to impart. Edinburgh was different (gruesome forecast of the Burke and Hare tragedies!), but of Aberdeen and Glasgow, he said:—"We know, gentlemen, that at least anatomy cannot be studied in those places with any hope of success. We are all, I believe, aware, and no one is more ready than myself to acknowledge the great talents and acquirements of the gentlemen at the head of the anatomical schools in those places, but we are also aware that they are destitute of subjects, and without subjects, without the necessary means, no talent in the teacher, no acquisition of which he can boast, no peculiar fitness for the office of instruction in the past will avail the student in his study of anatomy." From this Mr. Lawrence diverged to touch upon a point of which telling use was afterwards made in THE LANCET, that the by-law excluded the great provincial teachers from giving recognised certificates. "Need I mention," said the speaker, "Hey of Leeds, Hodgson of Birmingham, Martineau, Dalrymple, and Cross of Norwich, and Barnes of Exeter, names that will amply warrant me in stating my conviction that the surgeons of provincial hospitals are as fully competent in the instruction of students as the favoured body who are attached to the London hospitals?"

Mr. Tyrrell then rose, and supplemented Mr. Lawrence's remarks by relating the history of the College and so making clear that the ill-treatment of the Members by the Council of the royal chartered organisation was a perpetuation of the abuses enacted under a corrupt Corporation. He then proposed the following resolution:—"That the public and the members of the surgical profession very justly complain that the science of surgery has not been advanced nor its practitioners benefited either by the late Corporation or the present Royal College of Surgeons in London." Mr. Wardrop seconded the resolution, which was carried unanimously.

A second resolution was put to the effect that the new by-laws contained provisions of the most oppressive character, injurious to the rights and property of individuals, and calculated to increase the expense and difficulty of acquiring surgical knowledge and to serve the private interests of the ten examiners by whom these regulations were made. This also was carried unanimously. Next followed two resolutions dealing with the exclusion by one of these by-laws of eminent anatomists, English, foreign, metropolitan, and provincial, from the pecuniary and honorary benefits belonging to the position of a recognised teacher of anatomy or surgery. These were carried unanimously.

A Mr. Lloyd then brought forward a resolution condemnatory of the inaction of the College with regard to the library and the museum. The former he declared to be useless because of its incompleteness and because such valuable books as it did contain were not accessible to the members, who had paid for them with their fees. The latter, he said, was not only closed to the Members at all seasons when it would be of any practical use to them, but Hunter's splendid collection still remained uncatalogued twenty-four years after Government had presented it to the College for the promotion of medical science. Not the least contentious part of Mr. Lloyd's speech was a reference to the fact that the catalogue would now be exceedingly difficult to construct owing to an individual having destroyed John Hunter's inestimable manuscripts. The meeting cried *Hear hear! Name! Shame!* and *Sir Everard Home!*[3] and the resolution was passed unanimously.

The complaint with regard to the compulsory entrance of Members by the back door was also put in the form of a resolution and carried unanimously.

A resolution was then brought forward by a Mr. Wigan that a committee should be appointed to present to the Council of the College a remonstrance grounded on the foregoing resolutions and requesting that the grievances therein complained of should be remedied.

So far, as will be seen, the meeting had been remarkably at one in sentiment and language, but this resolution led to an animated discussion. It brought Wakley to

[2] Chapter XIX. of this Biography, May 16th, 1896, p. 1376.

[3] It may be necessary to remind the reader of the significance of this interruption. Sir Everard Home, the first President of the Royal College of Surgeons who used that title, was John Hunter's pupil, brother-in-law, and literary executor. In discharge of his executorship he destroyed Hunter's manuscripts about three years before the date of this meeting. He was and is generally believed to have made use of the papers in scientific writings to which he appended his own name and to have burnt them for fear of detection.

Digitized by Google

the front, who, while owning that he had been the author of the advertisements summoning those interested in the reform of the College to meet at the Freemasons' Tavern, said that he did not find the results as drastic as he had hoped. A lot of condemnatory resolutions forwarded to the College would certainly constitute a serious remonstrance to that body, but he did not believe that any remonstrance would be of avail. He wished to petition Parliament to recommend his Majesty to grant a new Charter, and one which allowed each Member to have a voice in the election of those persons who were to regulate the proceedings of the College in the prosperity of which he must feel a personal as well as a national interest.

His lengthy speech was listened to with mixed feelings by his audience. He was prepared to go much further than most of them, and many of his expressions of contempt for the present rulers of the College did not meet with response. The general feeling was, in fact, favourable to civil remonstrance at the time that Wakley rose to speak on the other side. But, said Wakley, one might as well remonstrate with the Devil as with this constitutionally rotten concern—his own words. Nothing would come of such a measure, and he urged the meeting to petition Parliament at once to abrogate the Charter. He carried the bolder spirits with him, although he frightened many conscientiously anxious in the cause of reform but not believing that such root-and-branch remedy was necessary. His speech was an eloquent effort—outspoken, combative, and closely reasoned. He set the meeting right on the legal procedure necessary to obtain an abrogation of the Charter, and summed up, with striking additions, those grievances endured by the Members, which had already been made the subject of unanimous resolutions. Gradually he carried his hearers with him. Dissentient cries grew less frequent and applause waxed more unrestrained. As he felt that he was winning he in his turn made concessions to the meeting, dropping his more contentious tone and appealing to their practical sense. He concluded by proposing a long amendment to Mr. Wigan's motion to the effect that a petition, founded on the resolutions already adopted should be immediately prepared and presented to the House of Commons praying for the appointment of a committee to inquire into the abuses thus revealed with a view to obtaining from the King a new Charter.

Mr. Lawrence, in putting the amendment to the meeting, said a few words in favour of the original motion, but Wakley had taken the sense of the assembly by storm and his views were endorsed by a large majority.

A committee of twenty persons was then appointed to prepare the petition to the House of Commons and the meeting adjourned.

(To be continued.)

THE PREVALENCE OF DIPHTHERIA IN CONNEXION WITH ELEMENTARY SCHOOLS.

DR. W. R. SMITH has recently presented to the London School Board an elaborate statistical report on the prevalence of diphtheria in London and elsewhere and its alleged connexion with the elementary schools. In the year 1894 the attention of the Board was forcibly drawn to the possible influence of aggregation in school on the spread of infection, by the publication of an important "memorandum" by the medical officer of health of the administrative county of London, which furnished evidence that school attendance since the year 1870 has been answerable for a *portion* of the increased prevalence of diphtheria that has been observed for some years past. Accordingly the School Board, by a resolution dated January, 1895, directed their medical adviser to report to them on the whole subject. Dr. Smith's report is divided into three sections. The first deals with the evidence as to local incidence of diphtheria in the past. The second with the diphtheria statistics available for London, and the third with Dr. Smith's personal investigations respecting 2000 cases of diphtheria occurring in 1895. Although the information contained in the first section is undoubtedly interesting in relation to the geographical distribution of diphtheria, it does not seem relevant to the present question; we shall therefore pass on to the second section, and endeavour to learn from it how far the evidence adduced by Dr. Smith proves his assertion that school influence plays but an unimportant part in the enormous increase of diphtheria during recent years in London. Before examining Dr. Smith's method of reasoning it may be useful to review for the benefit of those readers not conversant with the originals, the position which Mr. Shirley Murphy takes up in his memorandum, as well as in his presidential address to the Epidemiological Society. This position may be shortly summarised thus: The London mortality from diphtheria in 1871–80 was less than in 1861–70, but for some reason or other children from three to ten years of age shared less in the fall than did those under three or over ten years of age. If the London diphtheria mortality during 1891–93 be compared with that of former periods this special incidence is still more plainly marked upon children aged from three to ten years, these years being periods of exceptional diphtheria prevalence. Consequently if the rates prevailing in 1861–70 be compared with those of 1891–93 it appears that whereas in the later period the increase at all ages amounted to 196 per cent. and that among children under three and over ten years amounted to 173 per cent. and 53 per cent. respectively, the increase at ages from three to ten years amounted to as much as 309 per cent. There is therefore at the present time a greater tendency than there formerly was for children of from three to ten years of age to die from diphtheria, and close examination points to the year 1871, when the Education Act first became operative, as the year in which this increased prevalence first became conspicuous.

Dr. Smith in the course of a long argument sets himself to demolish Mr. Shirley Murphy's position. In the first place, he states that while the percentage of children attending elementary schools has increased from 25 per cent. in 1871 to 60 per cent. in 1893, the comparative death-rate at ages from three to ten years has remained throughout these years fairly constant. On examining Dr. Smith's Table 12, however, it is impossible to agree with this latter statement; for if the years be arranged in either decennial or quinquennial groups it will be found that with increase of school attendance there has been a gradual increase of comparative diphtheria mortality at the school ages. Again, Dr. Smith, commenting on the incidence of diphtheria on the several ages, admits that the fact that the decline during 1871 to 1880 was least at "school age" supports Mr. Murphy's contention. "But," he adds, "this cannot be said of the figures relatively to the recrudescence of the disease in 1881–90," inasmuch as "in England and Wales as a whole children aged from two to three years were most affected by this rise, while in London the increased incidence fell yet a year earlier." It is impossible not to recognise from this argument that Dr. Smith fails to grasp the point really at issue here—namely, whether the Education Act has actually contributed in any important degree to the recent prevalence of diphtheria; for he bases his statement on the incidences of mortality in 1871–80 as compared with 1881–90, whereas the Act had been passed in 1870. If Dr. Smith had compared the behaviour of diphtheria in 1861–70 with that in 1881–90, or with that in 1891–94 he would have found that his expectation "that any tendency to school infection would show itself in a marked manner at age four," would have been fully realised. In these comparisons the maximum increase is found, in each case, to be in children at ages from four to five years. Subsequent pages of Dr. Smith's report exhibit a similar fallacy, and suggest the notion that the writer fails to understand that two distinct factors have herein to be considered: the one, the natural behaviour of diphtheria in relation to age incidence, the other, the effect of the Act of 1870 upon this incidence; and that the effect of the Act can be appreciated only by contrasting the incidence of mortality in the several ages in periods respectively preceding and following the year 1870. It is to be hoped that having

Digitized by Google

regard to the importance of the subject, Dr. Smith will see fit to reconsider his conclusions in connexion with this part of his report. Dr. Smith next touches on the decrease in the diphtheria attacks notified in London at a time which corresponds with the interruption of school attendance by the summer holidays. He thinks that the decrease in the number of attacks is not due to diminished opportunities of infection, and while apparently admitting that there is a diminution of disease incidence about this time, he is evidently disposed to account for it by the migration of children from London for the summer vacation. But this explanation had already been considered by Mr. Shirley Murphy and held by him to be insufficient. Mr. Murphy has, moreover, shown that both in 1893 and 1894, when children from three to ten years are considered, the August decrease corresponds with the closing and the subsequent increase with the re-opening of the schools of the London School Board, *due allowance being made for the incubation period and for some delay in notification;* and, lastly, he has shown that the decrease in attacks among children aged under three years occurs somewhat later, "in a way to suggest that the attacks of children at the earlier age were due to infection from the older children, whilst the decrease in the attacks among the former was due to diminished opportunities of infection from the latter."

In conclusion, some reference must be made to Dr. Smith's inquiries into the origin of infection among about 2000 persons admitted into the hospitals of the Metropolitan Asylums Board. Using such aids for his inquiry as ambulance nurses and school teachers, Dr. Smith arrives at the conclusion that 7·6 per cent. of the cases at school age were due to school infection. Unfortunately, Dr. Smith's figures do not permit of the formation of a safe judgment as to how nearly this percentage represents the full proportion of attacks attributable to school influence, but if this proportion be assumed to be correct even Mr. Shirley Murphy could scarcely desire a more complete justification of the position which he has assumed. We must, therefore, express the opinion that the arguments in Dr. Smith's elaborate report fail to weaken in the slightest degree the force of the contention advanced in Mr. Shirley Murphy's memorandum and in his presidential address of 1894, and we trust that the educational and sanitary authorities of the metropolis will relax none of their endeavours to minimise the dangers which there still continues to be reason for associating with the aggregation of children in school under existing conditions.

THE POWERS AND DUTIES OF SANITARY AUTHORITIES.

NOTHING is more bewildering to those whose duties are more or less governed by the Factory and Workshops Acts than the cross references which abound in these documents of legislation; in addition to this the meaning of some of the sections are by no means clear and the re-codification of the existing Acts is most desirable. To disentangle as Dr. J. F. Sykes attempted to do in a paper read before the Sanitary Institute on Wednesday, April 15th, from the Factory and Workshops Acts, 1878 to 1895, the powers and duties of sanitary authorities was not an easy task, but Dr. Sykes is to be complimented on the way in which he accomplished it. Prefacing his remarks with some preliminary details and definitions he gave an apt illustration of the involved nature of the factory and workshop legislation.

The Factory and Workshops Act of 1878, Section 3, relating to effluvia, overcrowding, ventilation, &c., and Section 33, relating to lime-washing, washing, &c., applied to all factories and workshops. The same Act, Section 61 (1), exempted domestic workshops from Sections 3 and 33. The same Act, Section 101, exempted from the nuisances, Section (91) of the Public Health Act of 1875, all factories and workshops within the provisions of the Factory and Workshops Act, but relegated to the nuisances section above mentioned every other factory, workshop, or workplace. The Factory and Workshop Act of 1891, by Section 39 and Schedule 2, withdrew workshops within the Factory and Workshops Acts from Section 101 of the Factory and Workshop Act, 1778. The same Act of 1891 by Section 3 (1) withdrew workshops from Sections 3 and 33 of the Factory and Workshop Act, 1878. The net result of these cross references being that all extra-metropolitan workshops and workplaces are relegated by the Factory and Workshops Act, 1891, to Section 91 of the Public Health Act of 1875, and similarly Section 2 of the Public Health London Act, 1891, has now within its pale all metropolitan workshops and workplaces.

Confining his attention to nuisances special to workshops Dr. Sykes said it was the duty of a sanitary authority to see with regard to every workshop within a district:—1. That it is kept in a cleanly state. 2. That it is kept free from effluvia arising from any drain, closet, urinal, &c. 3. That it is ventilated in such a manner as to render harmless any gases, vapours, dust, or other impurities generated in the course of the work carried on therein. 4. That it is free from overcrowding—that is, that at least two hundred and fifty cubic feet of space per head are provided during ordinary working hours and four hundred cubic feet during overtime. 5. That the prescribed notice specifying the number of persons who may be employed in each room is duly affixed at the entrance to the workshop or that the fact is otherwise made known. 6. That a reasonable temperature is maintained in each workroom. 7. That it is lime-washed, cleansed, or purified when necessary for health as certified by an officer of the sanitary authority, bakehouses being excepted and otherwise provided for. 8. That it is provided with sufficient and suitable sanitary conveniences for each sex. 9. That note is made of the employment of protected persons in order that the factory inspector may be informed. 10. That the list of outworkers is inspected.

In addition to the ordinary requirements for a workshop already enumerated it is also the duty of a sanitary authority with regard to every bakehouse within its district to see:—1. That the inside walls, ceilings, &c., are (*a*) either painted or varnished every seven years and washed every six months, or are (*b*) lime-washed every six months. 2. That a sleeping place is effectually separated from any bakehouse in the same building, and is lighted and ventilated by an external window at least nine feet square, one half being made to open. 3. That a bakehouse cistern is separate and distinct from any water-closet cistern. 4. That any water-closet, earth-closet, privy, or ashpit is cut off from direct communication with a bakehouse. 5. That no drain or pipe for carrying off fæcal or sewage matter has an opening in the bakehouse. 6. That no bakehouse is in such a state as to be, on sanitary grounds, unfit for use as a bakehouse. 7. That no underground bakehouse is newly brought into use.

In the Public Health London Act, 1891, Section 141, the expression "bakehouse" means any place in which are baked bread, biscuits, or confectionery from the baking and selling of which a profit is derived. In the Factory and Workshop Act, 1883, Section 17 (1), it is provided that the sanitary authority shall enforce the sanitary provisions with regard to "retail bakehouses," and they are defined as places where the bread, biscuits, or confectionery baked in which are not sold wholesale, but by retail in some shop or place occupied together with such bakehouse. Section 36 of the Act of 1891 merely repeats the exception of bakehouses which are factories, and appears to be a redundant provision. The interesting point is the curious fact that in the metropolis wholesale bakehouses (not factories) are controlled by sanitary authorities, whereas outside the metropolis they are controlled by factory inspectors, another of the strange results of the complicated provisions of legislation by cross references. The sanitary provisions, the affixing of notices and abstracts, notice of occupation, and other provisions of the Acts, now apply to laundries, except to laundries of certain public institutions, domestic laundries, and laundries where not more than two non-residents are employed. By Section 27 of the Factory and Workshop Act of 1891 it was provided that the occupier of every factory and workshop and every contractor employed by such occupier shall, if required by order of the Secretary of State, keep a list of all persons employed, either as workmen or as contractor, outside the factory or workshop, and of the places where they are employed, such list to be open to inspection by any factory inspector or officer of a sanitary authority. In November, 1892, the Secretary of State made such an order with regard to the manufacture of wearing apparel, electro-plate and files, cabinet and furniture making and upholstery work. By Section 42 of the Factory and Workshop Act of 1895 it was further provided that the lists described in Section 27 of the Act of 1891 shall be sent on March 1st and September 1st in each year to the factory inspector of the district, and it was also provided that Section

Digitized by Google

27 of the Act of 1891 shall (by statute) apply to any place from which any work of making wearing apparel for sale is given out, as if that place were a workshop.

With reference to the relationship of the sanitary authority to the inspector of factories, by Section 26 of the Factory and Workshop Act of 1891 notices of the opening of new workshops, and by Section 41 of the Factory and Workshop Act of 1895 notices of the occupation of existing workshops, must be sent to the inspector of factories, and by him forwarded forthwith to the sanitary authority of the district. On the other hand, by Section 27 of the Public Health (London) Act, 1891, if the medical officer of health becomes aware of any child, young person, or woman being employed in a workshop, he must forthwith give notice of the fact to the factory inspector of the district. Section 29 of the Act of 1895 provides that any case of lead, phosphorus, or arsenical poisoning, and of anthrax contracted in any factory or workshop shall be notified by the medical attendant to the chief inspector of factories; that written notice of the case shall then be sent to the factory inspector and to the certifying surgeon, and be regarded as an accident, of which the latter is required to investigate the nature and cause. Now that the recently-appointed chief inspector of factories is a thoroughly experienced and well-known medical officer of health the objection raised to this provision ceases to have the weight it originally undoubtedly had; but this entirely new departure in the notification of disease will be watched with interest both by the public and the medical profession. Washing conveniences are also now required to be provided where lead, arsenic, or other poisonous substances are used in any factory or workshop. Further, the occupier of a factory or workshop is not allowed to employ any woman within four weeks after childbirth.

A few words must be devoted to the section of last year's Act, which provides that the occupier of any place where wearing apparel is made, cleaned, or repaired, or where it is given out for these purposes, or any sub-contractor of the occupier, is liable to a maximum penalty of £10 if he allows any wearing apparel to be made, cleaned, or repaired in any dwelling house or building occupied therewith, whilst any inmate is, to his reasonable knowledge, suffering from scarlet fever or small-pox. This will apply to tailoring, dressmaking, millinery, &c., as well as to laundrying, mangling, &c. It is rarely that an employer knows anything of the health of other persons residing in the same houses as his employés. He can only know of small-pox or scarlet fever if he be informed by his employé or by the sanitary authority, whose officer again would in turn have to be informed by the employé of the name and address of the employer, and there is no compulsion to disclose this, so that the working of this section must depend mainly upon the goodwill of the employé, to whom no provision of compensation for loss of employment is made. As medical officers of health are notified of all cases of scarlet fever and small-pox, what is really required is to give specific power to sanitary authorities to enforce removal to hospital of any cases of scarlet fever or small-pox occurring in any house where wearing apparel is made, cleaned, or repaired.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A MEETING of the Comitia was held on May 14th, Dr. SAMUEL WILKS, President, being in the chair. After the minutes had been read and confirmed, the PRESIDENT announced that Dr. Collingridge, Medical Officer of Health of the Port of London, had been nominated Milroy Lecturer for the ensuing year. It was also announced that the committee appointed to consider the Midwives Bill had not met, the Bill having been abandoned. The following gentlemen were then admitted to the Fellowship: Charles Montague Chadwick, M.D. Oxon., Harry Campbell, M.D. Lond., Arthur Gamgee, M.D. Edin., John Anderson, C.I.E., M.D. St. And., John Michell Clarke, M.D. Camb., Sir Hugh Reeve Beevor, M.D. Lond., Ernest Septimus Reynolds, M.D. Lond., William Hunter, M.D. Edin., William Aldren Turner, M.D. Edin., and Arthur Pearson Luff, M.D. Lond.

Formal communications were received from the headmaster of the school at Bury St. Edmunds, conveying the thanks of the governors, masters, and scholars for the portrait of Sir Thomas Watson; and from the Registrar of the General Medical Council announcing that the term of office of the representative of the College in the General Medical Council had expired. The Comitia proceeded to elect a representative and Sir Dyce Duckworth was re-elected by a large majority. The PRESIDENT bore testimony to the service rendered by Sir Dyce Duckworth to the interests of the College at the meetings of the General Medical Council, and after a few remarks from Sir DYCE DUCKWORTH the meeting adjourned.

THE AMERICAN MEDICAL ASSOCIATION.

THE New York *Medical Record* reports the proceedings of the forty-seventh annual meeting of this association, held at Atlanta, Georgia, on May 5th, 6th, 7th, and 8th. The proceedings comprised many matters of interest, of which we can now only notice the chief. The President (Dr. Beverly Cole), in his opening address, noticed what he called a lowering of the standard of the profession, a falling off from the days "when the medical man was a gentleman as well as a scholar." He found the reason of this, undoubtedly in the multiplicity of schools, with their bidding for patronage. He acknowledged efforts after a better state of things in many places, mentioning New York and Illinois, and "perhaps some other States," but doubted that the "commenced advance was not much more than a species of advertisement." He denounced the tendency of large life insurance companies to cut down examiners' fees, saying surely the fee of five dollars was small enough. He noticed that there was a tendency in foreign physicians to come to practise in the United States. Speaking of the Moscow Congress he regarded the exclusion of the English language as an insult to English-speaking people. He lamented the proneness of the clergy to endorse every quack nostrum, and was still more severe on certain medical men who give testimonials to proprietary remedies. In the conclusion of his address Dr. Cole deprecated the tendency to mutilate the human body by excessive surgery, fully admitting its honorable achievements. The appendix seems the organ most liable to such practices in the States, so that the Hon. John Temple Graves, in welcoming the association, alluded to this portion of the body as liable to special attack in a community so healthy as to leave little else for treatment by a faculty they were nevertheless all glad to welcome. The address in medicine by Dr. William Osler of Baltimore, and that in surgery by Dr. N. Senn of Chicago, were the chief features of the meeting. Dr. Osler, observing that humanity had suffered from three great enemies—fever, famine, and war—mentioned that three of the greatest benefits conferred on mankind had reference to fevers—the introduction of cinchona, the discovery of vaccination (which was duly celebrated at a later stage of the meeting), and the announcement of the principle of asepsis. He discoursed chiefly on typhoid fever, which he said was to-day the fever of their country. The address of Dr. N. Senn on "Some of the Limits of Surgery" was important. While magnifying surgery now founded on modern pathology and the new science of bacteriology, he deprecated the *furor operativus* manifested in special departments of surgery, and said that operative surgery had been carried to extremes. He showed the rapidity with which general infection may take place from the experiments of Schimmelbusch, who found micro-organisms in the spleen five or ten minutes after infection of a wound. We can only indicate a few of the subjects in which he indicated the limits of surgery in plain, not to say strong, language. Early resection or arthrectomy in cases of tuberculous joints he thought had been disappointing. In hundreds of cases he had got most satisfactory results from intra-articular and parenchymatous injections of iodoform and glycerin. Cure was obtained in one-half or two-thirds of uncomplicated joint cases. As regards the surgery of the abdomen, nearly 50 per cent. of cases subjected to radical treatment for malignant disease succumbed to the operation. He himself had opened the abdomen for malignant disease of the stomach in nineteen cases, and in only one was the disease limited to the organ first affected. He was especially plain in his words on the "greatest onslaught of modern surgery on the organs of generation, male

Digitized by Google

and female, and did not know where it was to end." "The mutilating work," he said, still continues, and he was especially severe on the recent graduate who, after watching the practice of a much-employed gynæcologist for a month or two, starts as a full-fledged specialist and is ready to extirpate the uterus, remove ovaries and Fallopian tubes, and sew up imaginary lacerations of the cervix and perineum. "The frequency with which women are being castrated is one of the most flagrant transgressions of the limits of the art of surgery," said Dr. Senn, and asked, "Where is this wholesale unsexing of our population to end?" He was scarcely more reserved in his plea in favour of conservatism in the treatment of prostatic hypertrophy. Finally, he declared that he had written without malice in the interest of sufferers and "as a plea for the recognition of good work done by the great mass and back bone of our profession—the modest, toiling, inadequately-remunerated general practitioner."

OYSTERS AND TYPHOID FEVER.

WITH reference to the special article which appeared in THE LANCET of Feb. 2nd, 1895, under the heading of "Oysters and Typhoid Fever" a good deal was said before a committee of the House of Commons recently on the subject of the possible communication of disease as a result of the consumption of oysters in a raw state. The Brighton Corporation are promoting a Bill in Parliament "To confer further powers upon the Mayor, Aldermen, and Burgesses of the Borough of Brighton," known as the Brighton Improvements Bill. Among the clauses is one allowing the Corporation or sanitary committee to make an order forbidding the introduction into Brighton of shell-fish from ponds or rivers contaminated with sewage in case of the medical officer of health attributing infectious disease in the borough to such shell-fish. Cases of typhoid fever have already been ascribed to the eating of sewage-contaminated oysters and other shell-fish from Shoreham Harbour, and it is alleged that in the year 1894 at least 40 per cent. of the cases of enteric fever originating in Brighton were ascribable to such shell-fish. However, this particular clause in the Bill has been struck out. It was strongly opposed by the two oyster merchants who are carrying on an extensive business with the favourite bivalvular mollusc in Shoreham Harbour—the port of Brighton, and a short distance from the borough. Dr. Newsholme in his evidence before the committee went fully into the cases which he ascribed to the eating of oysters and mussels from Shoreham Harbour, and was corroborated by Sir Joseph Ewart, M.D. Dr. Klein, F.R.S., gave the result of a bacteriological examination of water from the harbour and also of oysters submitted to him. There was, he said, sewage matter in both to a considerable extent, but he could find no definite trace of typhoid germs. He considered, however, that there was great risk of disease being caused under such conditions. Dr. Sharkey said that the general evidence of typhoid fever being spread by oysters was very strong. This concluded the evidence on this clause, and Sir William Marriott, Q.C., who, with Mr. Pember, Q.C., and Mr. A. V. Frere, appeared for the promoters, said he had no doubt the clause as it stood was very strong and he could quite understand the objection to placing so much power in the hands of the medical officer of health, who might seriously damage a trade. Any suggestion, he added, by which the action of the authorities might be made subject to an appeal to the Local Government Board or otherwise would be accepted by the Corporation; but after a deliberation of the committee in private the chairman (Mr. Mount) said they were of opinion that the clause should not be granted. During the proceedings the special article in THE LANCET was referred to. The article included a verbatim report of a bacteriological investigation of water from an oyster-bed in Shoreham Harbour and of oysters from the same source made by Professor Crookshank, M.B., Director of the Bacteriological Laboratory, King's College, London. The following extract practically summarises the report: "The question which I have been asked is whether oysters from this particular bed are likely to be injurious to the consumer. From the bacteriological investigation of the samples of water and of oysters submitted for examination I am of opinion that there is no evidence, from the bacteriological examination, which would lead me to condemn the oysters as dangerous or unfit for food. I am led to this conclusion by the absence of typhoid fever bacilli and by the absence of any septic micro-organisms, and by the fact that all the micro-organisms which I succeeded in isolating were perfectly harmless species. I would venture to add, however, that more than a bacteriological investigation is required to relieve public anxiety upon the question of a possible danger arising from the consumption of uncooked oysters."

THE OBLIGATIONS OF THE GENERAL MEDICAL COUNCIL, MEDICAL SCHOOLS, AND CORPORATIONS IN RELATION TO THE RIGHTS OF MEDICAL MEN.

AT a meeting on May 15th of the Select Committee of the Civil Rights Defence Committee on this subject, Mr. Timothy Holmes, F.R.C.S. Eng., in the chair, the resolution appointing this committee having been read, the resolutions of the meeting of the Civil Rights Defence Committee of Jan. 9th, 1896, were read as follows:—

1. That, as many of the great lay and medical public bodies will refrain from coöperating in the defence of the professional and civil rights entrusted to the committee until a strong consensus of opinion is aroused urging them to do so, the constituent bodies of the committee are asked to adopt resolutions in the sense of those adopted by the committee.

2. That the professional bodies represented on the Civil Rights Defence Committee be asked to use their influence with the medical schools which induce young men to enter the medical profession and with the General Medical Council, the universities, and corporations which confer upon them supposed rights, now formally declared to be held entirely at the pleasure of the Crown, acting by the judges, and ask them to unite in making good the rights which they take part in promising and which are now imperilled by the decision of the Court of Appeal.

General Graham's memorandum of Feb. 7th, 1896, to the medical papers requesting an expression of opinion on these resolutions was brought up and also THE LANCET of May 9th with an article on the work of the committee dealing with the obligations of the General Medical Council, medical corporations, and medical schools in relation to the rights of medical men, taking the same view as that adopted by the committee in the memorandum and resolutions, and declaring that these bodies are at present subsisting by holding out to men entering the profession false promises of rights now declared by the decision of the Court of Appeal to have no existence, and that it is incumbent on such bodies to discontinue receiving such moneys until the rights for which they receive them are vindicated.

Correspondence with the General Medical Council, the University of London, the Royal College of Physicians of London, the Society of Apothecaries, London, and St. Mary's Hospital Medical School inviting coöperation was laid on the table.

Lord Stamford's letter inviting the coöperation of the General Medical Council in defence of the rights confirmed by its certificate of registration was read. General Graham explained that the only reply had been from the solicitor of the Council, and not from the President, stating that the case is outside the scope of the Council and ignoring the grounds of the invitation.

Resolved:—

1. That a letter be drafted for the next meeting, to be addressed to the President of the General Medical Council for signature by the medical members of the committee, supporting the invitation conveyed by the President.

2. That letters be similarly prepared to be written to the President and Council of the following bodies: the Royal College of Surgeons of England, the British Medical Association, the Association of Fellows of the College, the Medical Defence Union, and the West London Divisions of the London and Counties Medical Protection Society, requesting each to act independently in support of this committee in earnestly inviting the coöperation of the General Medical Council.

Correspondence with the Society of Apothecaries was next considered, including an invitation to coöperate, to which no answer had yet been received.

Resolved:—

1. That a letter be drawn up for signature by the medical members of the committee supporting the invitation to the society to

Digitized by Google

unite in vindicating the rights of the society under its charter infringed in the violation of Mr. Anderson's rights as a Licentiate, and to use its influence with other guilds to unite in this defence of common rights.

2. That a report of the meeting be sent to the medical papers.

The meeting adjourned until to-day (Friday) at 6 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on the 14th inst., the President, Mr. CHRISTOPHER HEATH, being in the chair.

Mr. Harold J. Stiles was introduced and the President handed him the Walker Prize, and Dr. A. A. Kanthack was presented with the Jacksonian Prize.

A letter was read from Dr. J. S. Edkins, with a memorial signed by various professors and lecturers on physiology in the United Kingdom, requesting that certain alterations be made in the present examination in physiology for the Fellowship. It was resolved that Dr. Edkins should be informed that as the subject of physiology at that examination had been very fully considered so lately as eighteen months ago the Council did not see their way to reopen the question.

It was resolved that the annual meeting of Fellows of the College for the election of members of the Council should be held at the College on Thursday, July 2nd next, at 1 30 o'clock P.M. precisely, and that the meeting of the Fellows should be held on the same day at 5 o'clock P.M.

Mr. TWEEDY moved: "That a poll of the Fellows be taken respecting the motion passed at the general meeting of Fellows on the 2nd of January in favour of giving to the Members of the College direct representation upon the Council, and that a committee be appointed to prepare for the approval of the Council an elucidatory statement of the subject in question, together with the interrogatories which shall be submitted to the Fellows."—The resolution was carried and a committee was appointed.

A letter from Mr. W. G. Dickinson was read communicating a resolution adopted by the committee of the Society of Members respecting the resolution adopted by the Council on the subject of the representation of Members on the Council. A letter was also read from Mr. H. P. Dunn communicating a resolution adopted by the committee of the Association of Fellows, expressing regret that the Council had not adopted the resolution passed at the last meeting of Fellows, and the hope that the whole body of Fellows might be consulted on the subject. The receipt of the letters was acknowledged.

Mr. RIVINGTON moved: "That the following resolution carried at a previous meeting of the Council be rescinded—viz.: 'As the members of this Council represent the body corporate of this Royal College, and consequently its Members as well as its Fellows, it is the opinion of this Council that no further representation of the Members is desirable.'"—The motion was not carried.

THE SOUDAN EXPEDITION.

THERE has been but little to record in connexion with this expedition during the past week, nor does it seem likely that anything of importance will occur until the advance takes place. There appears to be little doubt that this may eventually assume the shape of a combined but double movement from Wady Halfa and from Suakin. The Indian force will reach Suakin in the course of another week, when the Egyptian troops garrisoning that place will be free to join the force operating in the Nile direction. We do not yet know what will be the hospital arrangements for the Indian contingent at Suakin. There will be a hospital—probably a field hospital—on shore, and possibly one of the ships may be utilised as a floating hospital, but we do not apprehend that (unless an outbreak of cholera should unhappily occur among them) there will be any large amount of sickness among the men of the Indian force, as they are acclimatised and accustomed to field service. All the transport arrangements have been completed for the transfer of the Egyptian garrisons on the Red Sea on their evacuating Suakin and Tokar when relieved by the Indian troops. There was a rumour that the North Staffordshire Regiment was about to be recalled from Wady Halfa to Cairo, but this appears to be quite unfounded. The regiment is much more likely to move in a southward than a homeward direction. In spite of the great heat (happily relieved at night by a breeze), the discomfort of sandstorms, and the monotony of the life, the troops are quite as healthy as could be expected. The hospital arrangements at Akasheh and Wady Halfa are described as very satisfactory. At Akasheh there is only accommodation for 150 sick, but the health of the troops—British and Egyptian—is, as we have said, good. An invalided British officer from Akasheh was recently conveyed successfully from that station to the Citadel Hospital at Cairo. The transport arrangements were excellent, and there were ample supplies of ice and necessaries *en route*. There are a great many rumours about the Dervish troops, but very little is really known of their actual or intended movements or as to the strength which can be brought into the field in defence of Dongola. It is said that Ferkeh, an outpost camp beyond Akasheh held by the Dervishes, has been evacuated; if so it will probably be occupied by the Egyptians. There is a good deal of activity still displayed among the military and War Office authorities at Cairo. The occurrence of an outbreak of cholera at Alexandria with some cases at Cairo is, of course, an unfortunate and embarrassing circumstance, which engages, naturally, a good deal of anxious attention on the part of the Egyptian Government and its sanitary department; but there is no reason to suppose that it will spread to posts along the Nile at a great distance from Egypt and affect the expeditionary force there.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6279 births and 3830 deaths were registered during the week ending May 16th. The annual rate of mortality in these towns, which had been 18·4 and 18·5 per 1000 in the two preceding weeks, declined again last week to 18·4. In London the rate was 17·8 per 1000, while it averaged 18·8 in the thirty-two provincial towns. The lowest rates in these towns were 11·7 in Brighton, 13·3 in Derby, 13·4 in West Ham, and 14·4 in Norwich and in Leicester; the highest rates were 21·2 in Liverpool, 22·0 in Salford, 23·0 in Sunderland, 26·0 in Plymouth, and 28·5 in Manchester. The 3830 deaths included 561 which were referred to the principal zymotic diseases, against 641 and 622 in the two preceding weeks; of these, 201 resulted from measles, 183 from whooping-cough, 72 from diphtheria, 40 from scarlet fever, 34 from diarrhœa, 30 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases occurred either in Brighton or in Preston; in the other towns they caused the lowest death-rates in Leicester, Derby, and Leeds; and the highest rates in Birkenhead, Croydon, Sunderland, and Manchester. The greatest mortality from measles occurred in Bristol, Portsmouth, Manchester, Sunderland, Birkenhead, and Oldham; from whooping-cough in West Ham, Huddersfield, Halifax, Birmingham, and Swansea; and from "fever" in Birkenhead. The mortality from scarlet fever showed no marked excess in any of the large towns. The 72 deaths from diphtheria included 43 in London, 5 in West Ham, 4 in Liverpool, 3 in Cardiff, and 3 in Birmingham. One fatal case of small-pox was registered in Cardiff, but not one in any other of the thirty-three large towns. There were 20 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 16th inst., against 16, 13, and 15 at the end of the three preceding weeks; 6 new cases were admitted during the week, against 8, 3, and 5 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2539, against 2534, 2523, and 2527 on the three preceding Saturdays; 293 new cases were admitted during the week, against 236 and 238 in the two preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 292 and 260 in the two

Digitized by Google

preceding weeks, further declined to 249 last week, and were 74 below the corrected average. The causes of 68, or 1·8 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Nottingham, Bradford, Newcastle-upon-Tyne, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Blackburn, Preston, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·0 and 18·9 per 1000 in the two preceding weeks, rose again to 19·3 during the week ending May 16th, and was 0·9 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 11·8 in Greenock and 15·4 in Perth to 19·9 in Aberdeen and 21·1 in Glasgow. The 563 deaths in these towns included 38 which were referred to whooping-cough, 17 to diarrhœa, 9 to measles, 4 to "fever," 5 to scarlet fever, 1 to diphtheria, and not one to small-pox. In all, 72 deaths resulted from these principal zymotic diseases, against 76 and 69 in the two preceding weeks. These 72 deaths were equal to an annual rate of 2·5 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 30 and 25 in the two preceding weeks, rose again to 38 last week, of which 24 occurred in Glasgow, 8 in Aberdeen, and 3 in Dundee. The deaths referred to measles, which had been 11 in each of the two preceding weeks, declined to 9 last week, and included 6 in Glasgow. The deaths referred to different forms of "fever," which had increased from 4 to 14 in the three preceding weeks, declined again to 4 last week, of which 2 occurred in Glasgow and 2 Edinburgh. The 3 fatal cases of scarlet fever corresponded with the number in the preceding week, and included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 88 and 110 in the two preceding weeks, declined to 92 last week, and were 17 below the number in the corresponding week of last year. The causes of 31, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate n Dublin, which had been 23·7 and 21·9 per 1000 in the two preceding weeks, rose again to 22·8 during the week ending May 16th. During the past seven weeks of the current quarter the death-rate in the city has averaged 23·3 per 1000, the rate during the same period being 18·7 in London and 17·7 in Edinburgh. The 153 deaths registered in Dublin during the week under notice showed an increase of 6 upon the number in the preceding week, and included 5 which were referred to the principal zymotic diseases, against 10 and 13 in the two preceding weeks; of these, 2 resulted from diarrhœa, 1 from scarlet fever, 1 from diphtheria, and 1 from whooping-cough, but not one either from small-pox, measles, or "fever." These 5 deaths were equal to an annual rate of 0·7 per 1000, the zymotic death-rate during the same period being 3·2 in London and 0·9 in Edinburgh. The 2 fatal cases of diarrhœa corresponded with the number recorded in the preceding week, while the mortality from scarlet fever was lower than in any recent week. The 153 deaths registered in Dublin last week included 30 of infants under one year of age, and 44 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded the numbers in any recent week. Four inquest cases and 8 deaths from violence were registered; and 70, or nearly one-half, of the deaths occurred in public institutions. The causes of 17, or more than 11 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

INDIA AND THE INDIAN MEDICAL SERVICES.

THE Queen has approved of the following promotion in the Indian Medical Service made by the Government of India: — To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon-Lieutenant-Colonel Andrew Deane, Bengal Establishment. Her Majesty has also approved of the retirement from the service of the undermentioned officers:—Brigade-Surgeon-Lieutenant-Colonel William Price, M.D., Madras Establishment; Surgeon-Lieutenant-Colonel Peter Johnston Freyer, M.D., Bengal Establishment. — *London Gazette.*

The services of Surgeon-Colonel T. J. McGann (Madras) are replaced at the disposal of the Military Department. Surgeon-Major R. Shore (Bengal), Medical Officer of the Mewar Bhil Corps, is appointed to officiate as Medical Officer, Kotah and Jhalrapatan. Surgeon-Captain H. R. Woolbert (Bengal), Medical Officer of the Deoli Irregular Force and of the Haraoti and Tonk Political Agency, is appointed to officiate as Residency Surgeon in Mewar, vice Surgeon-Major H. N. V. Harington. Surgeon-Lieutenant-Colonel P. A. Weir (Bengal), Residency Surgeon in Nepal, is appointed to officiate as Medical Officer of the Deoli Irregular Force and of the Haraoti and Tonk Political Agency. Surgeon-Major R. Neill Campbell, Officiating Senior Medical Officer, Port Blair, is appointed to be *ex-officio* Assistant Superintendent in the Settlement. Surgeon-Lieutenant-Colonel J. W. Clarkson is appointed to be Sanitary Commissioner for the Government of Bombay. Surgeon-Captain W. E. Jennings has delivered over the charge of the Shikarpur Prison. Surgeon-Major J. Crimmin, V.C., and Surgeon-Captain W. E. Jennings, M.B., have respectively delivered over and received charge of the office of Health Officer of the Port of Bombay.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Surgeons: A. E. Merewether, W. R. Center, C. M. Beadnell, W. S. H. Sequeira, J. G. Fowler, J. C. G. Reed, E. G. E. O'Leary, W. M. Keith, E. Sutton, W. E. Matthew, M. L. M. Vaudin, W. H. Thomson, J. W. Craig, W. L. Martin, A. T. Wysard, W. J. Stitt, and S. Croneen to the *Victory* for Haslar Hospital; A. W. B. Livesay to the *Victory*, additional for disposal; A. F. Harper to the *Scylla*; and J. H. Stenhouse to Plymouth Division of Royal Marines.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Thomas J. Compton to be Surgeon-Major.

VOLUNTEER CORPS.

Artillery: 1st London (City of London): Alfred Allport, gent., to be Surgeon-Lieutenant. The Highland: Surgeon-Lieutenant G. A. Lang, M.B., to be Surgeon-Captain. *Engineer: Fortress and Railway Forces, Royal Engineers:* 1st Middlesex: Surgeon-Lieutenant W. H. Bourke, M.D., to be Surgeon-Captain. *Rifle:* 4th Volunteer Battalion the Norfolk Regiment: George Lowe, M.D., to be Surgeon-Lieutenant. 2nd Volunteer Battalion the Royal Welsh Fusiliers: Evan Thomas Hughes, gent., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Charles Cecil Bullmore, gent., to be Surgeon-Lieutenant. 1st (Pembrokeshire) Volunteer Battalion the Welsh Regiment: Surgeon-Lieutenant W. L. Hughes resigns his commission.

THE EXAMINATIONS FOR NAVAL SURGEONS.

The under-mentioned gentlemen who competed on the 4th inst. and following days at Examination Hall, Victoria Embankment, for appointment as Surgeons in the Royal Navy have been granted commissions:—

Name.	Marks.	Name.	Marks.
A. E. Merewether, M.B. ...	2712	W. E. Matthew	2307
W. R. Center, M.B.	2680	M. L. M. Vaudin, M.B. ...	2260
C. M. Beadnell	2631	W. H. Thomson	2181
W. S. H. Sequeira, M.B. ...	2605	J. W. Craig, M.B.	2175
J. G. Fowler	2494	W. L. Martin	2171
J. C. G. Reed	2446	A. T. Wysard	2161
E. G. E. O'Leary	2393	W. J. Stitt	2109
W. M. Keith, M.B.	2365	S. Croneen	2055
E. Sutton	2318		

NAVY ESTIMATES.

In the recent debate on the navy estimates, when the House went into Committee of Supply, there was extremely little of a medical character touched upon beyond some remarks by Admiral Field on the lady nursing system introduced into the naval hospital service, with special reference to Malta, and the old grievance about the toll exacted at the bridge leading to Haslar Hospital. Mr. Macartney concurred in the remarks of the gallant admiral as to the valuable services of the nursing sisters, adding that he understood there was a head nursing sister at Malta. With reference to the

Digitized by Google

toll-bridge at Haslar he was prepared to consider any representations that might be made.

THE LEE-METFORD BULLET.

It will be remembered that experience in India during the Chitral expedition was not altogether favourable to this missile in that it was not found to possess sufficient "stopping" power. We noticed, too, that a similar complaint was made of the bullet by the defenders of Bulawayo in their encounters with the Matabeles, and it was alleged that on this account the Martini-Henry had been substituted for the Lee-Metford rifle. As the result of experimental investigations in India it is announced, however, that by a slight modification in the Lee-Metford bullet this defect has been completely overcome.

THE MILITIA AND THE SPREAD OF SMALL-POX.

We recently printed a letter from a correspondent calling attention to the danger of importing small-pox from Gloucester into hitherto healthy districts by assembling men from the affected city and district for their annual militia training. We are glad to see, therefore, that Her Majesty has been advised to dispense with the calling out of the third and fourth battalions of the Gloucestershire Regiment, an order in respect to which appears in the *London Gazette* of May 15th.

Surgeon-Major T. B. Moffitt, A.M.S., will arrive at Netley for duty on the 23rd inst.

Correspondence.

"Audi alteram partem."

"X" RAYS: INSTANTANEOUS PHOTOGRAPHY AND EXPERIMENTS UPON THE HEART AND OTHER SOFT TISSUES.

To the Editors of THE LANCET.

SIRS,—Considerable attention has lately been paid to the use of fluorescent screens and special plates with a view to the reduction of the time of exposures. The object of this communication is not to minimise the importance of any aid which may be placed in the hands of a surgeon, because whatever success should attend the ordinary and simpler methods it is not unlikely that instances may occur for which we should require every facility at our disposal. In my previous communications, however, I have pointed out that just as we desire good sunlight in ordinary photography more than quick plates, so in this work a good Crookes's tube is what we most need. The experiments below have all been done with the ordinary focus tube, Paget XXXXX plates, and hydrokinone developer. With regard to the tubes I have made many modifications by experiment, such as increasing the size of the aluminium concave disc to one and three-quarter inches in diameter. What I find is most important, however, is the proper vacuum. Hence I am more particular than ever, when I wish a tube for special work, to superintend the exhaustion and to test it on the fluorescent screen before taking off the pump. Another improvement is to be got by watching the current passing through the coil. I found that the fluorescence with the mercury interruptor was much greater than that with the ordinary platinum spring, and on testing with Lord Kelvin's cell tester and ampèremeter I found that when the current across the terminals was as high as 17 ampères during the time of exposure and when the spring was vibrating the meter would not register more than 1 ampère. On the other hand, with the mercury interruptor one single flash was enough to send it up to something like 5 or 7 ampères. Instead, therefore, of counting the exposures in minutes and seconds in instantaneous work I use the mercury interruptor and register the number of flashes in the tube due to each vibration of the interruptor. By this means I have photographed the bones of the hand with one flash of the tube and obtained the best negative I have ever taken of the bones of the hand with ten such flashes. The current across the terminals during this experiment registered 10 volts and 10 ampères and the spark was from 10 to 11 inches in length.

This is not, however, the only advantage of the method described, because by making a series of observations on the fluorescent screen I was able to distinguish shadows of many of the soft tissues of the body. As stated in a report of the demonstration given to the British Laryngological Association, I have seen and photographed the deep structures of the neck, including the larynx and tongue. I have now distinctly seen the cardiac area in the living subject, showing its right and left borders, base, and apex. In a photograph of the same the relationship of the ribs, clavicle, &c., are also well defined. The diaphragm covering the liver on the right side is also well seen. I have photographed the normal heart in a number of cases (with its pericardial covering of course), and in some of these experiments with the ordinary tube it did not take more than eight minutes' interrupted exposures. In one, a young subject, hypertrophy of the right ventricle with enlargement of the liver could be distinctly made out. I would add one more note in passing: the vacuum of every tube changes during exposure, but with a little experience and by means of a Bunsen's flame it can be easily brought back to the condition which gives the maximum number of "x" rays. For the above reasons I have not found quick plates or fluorescent screens of very great advantage in photography.

I am, Sirs, yours faithfully,

JOHN MACINTYRE, M.B. Glasg., F.R.S.E.

"A RECORD OF THE INFECTIOUS DISEASES OCCURRING AMONGST 400 ADOLESCENTS DURING A PERIOD OF TWENTY-FIVE YEARS."

To the Editors of THE LANCET.

SIRS,—The profession is indebted to Dr. Clement Dukes for the data he has given as to the incidence of infectious disease among 400 boys, presumably the average population of Rugby School. Although I have no desire to discuss his figures as a whole, yet I should like to offer some general remarks upon those that deal with ophthalmia—a term which as employed by Dr. Dukes is by no means free from obscurity. So accomplished a physician need be scarcely reminded that at least three contagious eye conditions are included under that word—namely, (1) muco-purulent and (2) purulent ophthalmia, and (3) acute trachoma. According to my experience each of these is a specific malady due to a particular micro-organism and having a different meaning. Yet the writer makes no attempt in his communication to distinguish between them. Again, he employs the phrase "granular lids" without any qualification whatever. His readers are thus left in doubt whether by that expression he means mere follicular disease or the far more serious affection, trachoma, both of which in a certain sense may be said to be marked by a granular state of the conjunctiva. These ambiguities make it difficult to estimate the meaning of Dr. Dukes's figures, and appear to me to rob his communication of whatever scientific value it might otherwise possess. Apart from this looseness of expression, I gather from Dr. Dukes's paper that ophthalmia has for long been endemic in the school with which he is connected. His figures, at least, will bear no other interpretation. For example, the cases have ranged from 1 to 31 per annum, and once only, since 1874, has the malady been wholly absent. The yearly average stands at 8·52 (not at 7·16, as the writer makes it appear in Table III.). This, then, is the state of things that has prevailed for many years, "notwithstanding the greatest care, the provision of hygienic surroundings, and even of 800 cubic feet for dormitories." I feel tolerably certain that in a Poor-law school such an unfortunate condition would not be permitted to continue without repeated and vigorous protest from the Press, both lay and medical. Some of these maligned barrack schools can certainly show a better record. Take, for instance, the Central London District School, with an average population of more than 800, and compare its annual percentage of ophthalmia with that recorded by Dr. Dukes for the last five years. The figures come out as follows:—Ophthalmia among the State children: 1891, 1·87 per cent.; 1892, 1 62 per cent.; 1893, 1·12 per cent.; 1894, 0·5 per cent.; and 1895, 0·5 per cent. Among Dr. Dukes's adolescents: 1891, 6·25 per cent.; 1892, 5·25 per cent.; 1893, 7·75 per cent.; 1894, 4·25 per cent.; and 1895, 4·5 per cent. It will at once be seen that there is a considerable balance in favour of one of the very Poor-law schools concerning which Dr. Dukes remarks that its inmates "are apparently as

Digitized by Google

grossly neglected in all sanitary precautions as were our prisoners in the sixteenth century." The foregoing comparison, furthermore, takes no count of two important facts: first, that the State schools admit young children, who are notoriously more subject to ophthalmia than "adolescents"; and secondly, that many of those received are in a delicate state of health, either from heredity or upbringing. Were these two factors given their due weight the comparison instituted would tell still more in favour of the Poor-law school. Dr. Dukes lays it down that the prevalence of ophthalmia "is the surest test of unsanitary conditions where the young are concerned, especially the want of soap and water and fresh air." I am not disposed to dispute this dictum, the logical outcome of which clearly is that the hygienic state of the Central London School is better than that of the institution from which Dr. Dukes draws his figures.

I am, Sirs, yours faithfully,

SYDNEY STEPHENSON,

Ophthalmic Surgeon to the North-Eastern Hospital for Children; Surgeon to the Ophthalmic School, Hanwell, W.

Welbeck-street, W., May 12th, 1896.

QUALITY OF MILK.

To the Editors of THE LANCET.

SIRS,—Medical men not infrequently give directions for infants to be fed on milk produced by *one cow*, but they seldom or never take the necessary precaution of warning parents to see that the cow selected for the purpose is *in calf*. The milk of a healthy cow that is *in calf* can be safely used at all times provided it is fed on suitable food, and a delicate infant may derive all the benefit hoped for by the daily supply of milk so produced. But it seldom happens that cows kept in urban districts are *in calf*. Town dairymen usually buy newly-calved cows and milk and fatten them simultaneously. Such cows may come in service every three weeks, and whenever they happen to be in service their milk is more or less unwholesome and may prove to be absolutely poisonous if given to a delicate infant. When an *in-calf* cow is not available it would be far better to use the mixed milk from an entire herd rather than to run the risk of having milk supplied from a cow that may have been in service at the time the milk was drawn.

I am, Sirs, your obedient servant,

ROBERT E. TURNBULL.

Claremont, Shrewsbury, May 11th, 1896.

"THE BATTLE OF THE CLUBS."

To the Editors of THE LANCET.

SIRS,—My attention has been drawn to a letter in your issue of May 2nd signed "Sophocles" the paragraphs of which are numbered from one to seven, my reply to them shall be in the same order only referring to numbers.

No. 1. Only four Associations use the word "Aid," which is a misnomer, the Alliance has nothing to do with names but did suggest an alteration.

No. 2. Such a resolution was not submitted to the meeting and therefore could not be discussed.

No. 3. In abstract statistical reports the mode by which the Value is attained cannot be set forth, and misinferences have been drawn from them, yet this was not discussed, nor any instructions given to me respecting it. I refer "Sophocles" to THE LANCET of November 7th, 1895, in which is given "partly" how one of the most valuable of these F.S.M.A. obtained its value; namely, by money raised four months prior to opening the Institution by Entrance Fees, Bazaar, and special donations. The salaries paid the Medical Department have been and will continue to be inserted in the Alliance Reports. As medical statistics are frequently computed, and the nature of what is termed Visits, Consults, and prescriptions are of no value, difficult to understand through the modes in which they are given in Associations reports and the various manners in which different Doctors compile them, the Conference after discussion declared them unnecessary and misleading, and ordered them not to be printed in their Report. This does not effect Associations, who doubtless will in future as in the past print the work of of their Institions.

No. 4. No application was received from the medical officer of Tonbridge Wells and such advice as named was not given to the Tunbridge Wells Association.

No. 5. The Registering of the Alliance (which is unnecessary) could only give security to its funds which are small and could not effect any Association, the idea of securing greater power over the profession was never thought of.

No. 6. No such resolution was submitted or discussed nor was any such advice given to any Association about their Surgeons as named in this paragraph. The Lincoln Telegram was to its own Delegates, and altho read to the meeting no instruction was asked and none given, nor was a reply sent.

No. 7. This Appears the freest from error of any of the statements made by "Sophocles." Yes, a deputation was appointed who in due time will wait upon the General Medical Council, and should they, "The G.M.C." attach any importance to an Anonymous letter doubtless the deputation will be able to answear any query arising therefrom.

This is the firstime I have replied to an Anonymous writer, and "Sophocles" will have to sign his own name and whereabouts if he desires a further reply. Our Report is in printers' hands; copies will be sent to the G.M.C.

I am, yours faithfully,

Markham-street, York, May 11th, 1896. JOHN BROWN.

"THE BRONCHITIS KETTLE, POULTICES, AND OVER-FEEDING IN ACUTE LUNG AFFECTIONS."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of April 18th Dr. de Havilland Hall, writing upon the treatment of bronchial and pulmonary diseases, deprecates in the main the use of the "bronchitis kettle" and the application of poultices generally, but extols in lieu the use of "Gamgee tissue or cotton wool upon which is sprinkled some stimulating liniment." Some fifteen years since or more I read a letter in THE LANCET by a medical man advocating the application of olive oil to the chest and between the shoulders in all chest complaints of an inflammatory nature, the patient to be also enveloped in a jacket of cotton wool. I have adopted this practice ever since and have been delighted with its results. Especially have I been pleased with this form of treatment among children of all ages, and so satisfied have many of my patients also been with it that they often make use of the olive oil and cotton wool before—or instead of, alas!—sending for me.

I am, Sirs, yours faithfully,

Putney, S.W., May 12th, 1896. J. FFRENCH BLAKE.

THE EVOLUTION OF THE SURGICAL TREATMENT OF THE BROAD LIGAMENT PEDICLE.

To the Editors of THE LANCET.

SIRS,—Mr. Lawson Tait has done good service to the literature of this important subject by his paper in THE LANCET of May 16th, in drawing attention to the superiority of the actual cautery in the intra-peritoneal treatment of the stump. He also rightly insists that, to be effectual, the stump must be thoroughly "cooked" and not merely seared. I find, on reference to my books, that I followed this method at the Hospital for Women in 1873, and I suppose I afterwards took to using the intra-peritoneal ligature as being more rapid. Finding that the petroleum cautery often did not do more than sear the stump, and that there was consequently a risk of oozing, I had made an oblong block of iron, and this being thoroughly heated in a fire was applied to the stump above the cautery clamp, so that the heat being conveyed to the steel flanges of the clamp thoroughly cooked the stump and reduced the risk of hæmorrhage to a minimum. While Mr. Lawson Tait's ingenious electric cautery clamp promises to be most effectual, yet in ordinary practice the slightly complicated apparatus might militate against its universal adoption.

I am, Sirs, yours faithfully,

Harley-street, W., May 18th, 1896. HEYWOOD SMITH.

To the Editors of THE LANCET.

SIRS,—Absence from home prevented me sending you revised proof in time, correcting a few mistakes and making the additional statement that we have now applied the instrument to seventeen pedicles with uniform success. The first two were cases operated on by my late assistant, Dr. Howard Morgan of Brisbane. The last case was one where

Digitized by Google

the pedicle was so rotten that no ligature could have held, as everything tore on the slightest tension. The hæmostat completely shrivelled the pedicle and the patient is now (sixth day) quite well.—I am, Sirs, yours faithfully,

Birmingham, May 18th, 1896. LAWSON TAIT.

*** The makers of the new hæmostat are Messrs. Philip Harris and Co. of 144 and 146, Edmund-street, Birmingham.

"MATERNAL SYPHILIS."

To the Editors of THE LANCET.

SIRS,—It appears to me that Dr. Coutts's own statement in his first lecture is in favour of the possibility of maternal syphilis in every case, as well as in favour of the view that immunity to syphilis is the equivalent of the acquisition of the complaint itself. Both these views Dr. Coutts takes exception to in his letter of May 9th. The statement I refer to is: "There are other inherent difficulties in the way of estimating the paternal influence as regards the frequency of transmission of syphilis and its severity in the infant. One such difficulty lies in the fact that the mother may possibly have been affected in the ordinary manner although she may exhibit no signs of the disease, and then it becomes a matter of impossibility to rightly assign to either parent his or her due share in the production of the complaint." In my letter of April 18th I ventured to suggest that syphilis or its sequelæ was more prevalent in parous women than children's hospitals seem to indicate. Dr. Coutts in his first lecture stated that "a very large proportion of the mothers of syphilitic infants exhibit no outward evidence of the complaint even after prolonged and careful search." In his letter of May 9th he states his impression is that "mothers who are apparently free outnumber those where she is obviously syphilitic by three or four to one." If it can be shown that immunity is only apparent and not real, another argument, I think, must be conceded to primary syphilisation and maternal syphilis, especially if we bear in mind Dr. Coutts's disbelief in "syphilis by conception." I did not intend to give the impression of any dogmatic view. I thought I was careful to say I had no complete or comparative statistics, but that I had collected cases of syphilis in parous women in whom no history of previous illness could be obtained. I shall hope before long to bring forward the cases on which my letter of April 18th was founded, and I hope the experience of others will then be elicited. In the meantime I gladly admit with Diday that "nothing is constant in syphilis." The truth of such a remark is emphasised in these days when fixed belief in the absoluteness of Colles' observations and in the contagious character of hereditary syphilis is being shaken.

I am, Sirs, yours faithfully,

JOHN A. SHAW-MACKENZIE.

Savile-row, W., May 11th, 1896.

FOUNDATION OF A JENNER MEMORIAL MEDAL.

To the Editors of THE LANCET.

SIRS,—At the annual meeting of the Epidemiological Society of London, which was held at the address given below on May 15th, it was unanimously resolved, having regard to the historical connexion of the society with vaccination and other preventive measures, to found a medal in memory of Edward Jenner on this the centenary celebration of a discovery which has been attended with such brilliant results in the direction of preventive inoculation. It is proposed that the medal shall be founded with a view to the promotion of epidemiological research, and that it shall be bestowed from time to time by this society on persons who shall have contributed to the knowledge of preventive medicine. It is felt that in the foundation of a memorial of this character the members of the medical profession should be afforded an opportunity of taking part. Donations (not exceeding one guinea) may be sent to the honorary treasurer, 6, Hereford-mansions, Bayswater, W., and a list of donors to the fund will be issued in due course.

We are, Sirs, your obedient servants,

SHIRLEY F. MURPHY, President.
R. D. R. SWEETING, Treasurer.
H. TIMBRELL BULSTRODE, Hon. Secretary.

11, Chandos-street, Cavendish-square, W., May 18th, 1896.

"DECIDUOMA MALIGNUM."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 16th I am reported as having in all seriousness suggested to the Obstetrical Society at their last meeting the adoption of the terms "syncytioma" and "trophoblastoma" instead of "deciduoma malignum." It will hardly be necessary for me to state that the suggestion was playfully offered to those who seek a pleasure in discovering old diseases under new names. I am satisfied with the terms in general use and find no necessity for new ones.

I am, Sirs, yours faithfully,

St. John's Wood, May 19th, 1896. A. A. KANTHACK.

"THE ARMY MEDICAL STAFF."

To the Editors of THE LANCET.

SIRS,—In the number of THE LANCET dated May 16th "An Old Subaltern," who dates his experience from forty years ago, most favourably contrasts the position of the officers of the Army Medical Department of that date with the somewhat degraded position which they now hold. Your present correspondent can date back not only forty years but fifty-seven years ago, commencing from 1839, and during nine years he was first assistant surgeon of the 71st Highland Light Infantry and finally surgeon of another distinguished Scotch regiment, and can quite confirm what "An Old Subaltern" says. Were I again a young man, with or without means, nothing would induce me to enter the Army Medical Department as now constituted, knowing as I do what it was in former times. Permit me briefly to state what changes I would make in the Department were I in authority. First and foremost, I would restore the old regimental system and a suitable staff of non-regimental officers for garrison, detachment, and extra regimental duty. Secondly, I would abolish the titles of surgeon and assistant surgeon and replace them by senior and junior medical officer. Surgery is only one branch of our profession, and in peaceful times perhaps the least prominent in the practice of the army. Thirdly, I would recommend that in the choosing of candidates for commissions those holding university degrees should be preferred, and seeing that the possession of such degrees gives precedence, according to the official reports of presentations at her Majesty's Levées, before all military rank unsupported I would abolish that most ridiculous innovation whereby the nominal titles of combatant officers are tacked on to the titles of medical officers. Never was a more senseless scheme devised and carried out, or one more liable to place medical officers in false positions in society. Let it be abolished, retaining, however, such nominal grades as will secure to medical officers, according to their rank and length of service, their proper position as to choice of quarters, allowances, and precedence in all regimental non-combatant affairs, such as those connected with mess and other matters, to the carrying out of which they contribute their shares.

I venture to send these few suggestions, being, I believe, nearly, if not, the oldest retired medical officer of her Majesty's service now in existence.

I am, Sirs, your faithfully,

May 20th, 1896. J. D. J.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Ingleby Lectures.

THE Ingleby Lectures for the present year are to be delivered on June 10th and 17th at Mason College by Mr. Priestley Smith, the subject being the Mechanism of Binocular Vision and the Causes of Strabismus.

Sudden Death after Extraction of a Tooth.

A singular termination to an apparently simple operation was the cause of a coroner's inquiry at Brierley Hill on the 16th inst. A woman had a double tooth extracted by a registered dentist; a few minutes afterwards she expired. No chloroform or drug had been used during the operation. A post-mortem examination showed that death was due to failure of the heart's action from natural causes. Had an

Digitized by Google

anæsthetic been given or any new drug tried no doubt the result might have been credited to its use. It is important to recognise the fact that death occasionally takes place when no agent of this kind is used.

Action against a Dentist.

An action was brought in the County-court on the 9th inst. by a labourer against a druggist to recover damages for injuries sustained through the extraction of a tooth. The plaintiff went to the defendant's shop where the assistant proceeded to operate upon a double tooth. Something came out, the tooth was broken, and the plaintiff protesting against the rough usage he had been subjected to consulted his club medical officer, under whose treatment he remained for five weeks subsequently, and who found that the jaw had been splintered and the tooth broken. The patient afterwards went to the hospital and several pieces of necrosed bone were removed. Evidence was given as to the competency of the druggist and as to the accident being liable to occur in skilled hands. The jury found a verdict for the defendant.

The Workhouse Scandals.

An inquiry by one of the Local Government Board inspectors was recently held at the Birmingham Workhouse into the circumstances connected with the death of two inmates. The subject has given rise to some correspondence in the local press and to a considerable amount of discussion upon the administration of the house. The inspector stated at the opening that the inquiry was not suggested by the guardians, but from the amount of expression of opinion it was thought better to have the whole matter thoroughly gone into by an inspector who could examine witnesses on oath. The inquiry was a little unusual because it arose not upon any charge made by the guardians against their officers and they had not asked for it, though they made no objection to it. His instructions were to inquire into the circumstances connected with the deaths of the two persons, not to hold a general sort of investigation. Various witnesses were called and examined. The result of the proceedings is awaited with interest.

Birmingham Will Case.

The outcome of the appeal in this case, which was dismissed on the 15th inst., has settled definitely the former verdict for the plaintiff. The case was tried by a special jury at Birmingham on March 27th. The testator died in September, 1895, and the ground on which it was sought to set the will aside was mental incapacity, in support of which evidence was brought forward to show that the testator's memory was failing, that he was of dirty habits, and that he had delusions about poverty and persecution. It was alleged that undue influence had been used and that the testator was insane. At the time of the trial a large array of expert evidence was brought to bear on either side. The issue involved a large sum of money—some £30,000—and great interest was exhibited in the course of the trial, which will probably stand as a record case.

Hospital Saturday Collections.

At West Bromwich the recent collections in aid of the District Hospital amounted for the day to £514 odd, being a considerable increase compared with last year. The Oldbury Hospital Saturday Committee in pursuit of the same cause received also £347, an increase of £30 upon last year. It is gratifying to note the augmentation of these charitable funds in the district as indicating a revival in trade and consequently increased support for the institutions in the locality.

May 19th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Trafford Park.

ACCORDING to the most recent estimate by the medical officer of health the population of Manchester is 531,697, and there is every prospect of its steady and perhaps rapid increase. For this population, a very large proportion of which is of the working class, the open spaces and parks cover altogether 311 or 312 acres—not a very extravagant provision—and on their purchase and development £306,000 have been spent. It seems that Glasgow possesses 881 acres and has spent £473,000 on purchase alone, while Liverpool has spent £783,000 on 854 acres. There is now an opportunity of acquiring the extensive area of Trafford Park, containing 1180 acres, which Sir Humphrey de Trafford wishes to sell. An idea of its extent may be given by saying that it is three times the size of Hyde Park, which has 390 acres. As the *Manchester Guardian* says: "It has lain by Manchester, secure in its seclusion, century after century"—indeed, from before the Norman Conquest; "at the western gate of the city," in the picturesque but, alas, inaccurate phraseology of another local paper, for the city has no gates. It is near the county cricket ground and one of its main entrances is just opposite that of the Botanical Gardens, while from the Central Station passengers could be set down at the park in five minutes, and easy access can also be obtained from its extensive frontage to the Ship Canal. The inner or deer park of 700 acres, in which the hall is situated, is well wooded and has a lake of some size, while the flower gardens round the hall are of rare beauty. Belts of fine timber enclosing the greater part of this inner park shut out from view the smoke of Manchester and Salford. It is believed by those who may be considered competent to judge that in a comparatively short time by the development of the "fringes" of the outer park—along the canal frontage for business and on the other side for residential purposes—the cost would soon be reduced to a penny on the rates, or even to the vanishing point, especially when it is remembered that Sir J. Harwood and the Waterworks Committee, by judicious management, were able to spend £3,000,000 on the Thirlmere scheme without adding a single penny to the city rates. There is an immense population of boys and young men in Manchester eager for out-door exercise and recreation, which they greatly need, and it becomes more and more difficult to find the necessary space. The park is the only ground sufficiently near the city where large agricultural shows could be held. The Hulme Cavalry Barracks are not far away, but the removal of the troops from Manchester on account of the want of suitable exercise ground, which the park would supply, has long been talked of; the Home Office is pressing the corporation for a review ground for the police, while one is wanted also for the Volunteers. It is estimated that the removal of the troops would entail an annual loss of £20,000. The arguments in favour of purchase are irrefutable, and were it not for the heavy responsibilities which he city will, for some little time at all events, have to bear in connexion with the Ship Canal the corporation would no doubt at once take steps to acquire a property which, from the public health point of view, to say nothing of the public convenience, is of such inestimable value. A meeting of the city council was held yesterday to consider this matter, and after a long discussion a resolution was carried, with a few dissentients, appointing a committee to consider the subject of the purchase of the park. If £3,000,000 could be spent for water without adding to the rates, there is not much doubt that with the special opportunities which the park gives for recoupment the £300,000 or £350,000 said to be required for its purchase would soon cease to be any addition to the burdens of the city.

Charitable Bequests.

By the will of the late Mr. Thewlis Johnson of Manchester, whose personalty is sworn at £446,304 3*s.* 10*d.* net, the Manchester Royal Infirmary, the Ancoats Hospital and Dispensary, the Derbyshire Royal Infirmary, and the Bishop of Manchester's Fund receive £500 each.

Withington Recreation Grounds.

Withington, Didsbury, and Chorlton-cum-Hardy are rapidly growing suburbs of Manchester, and there seemed a probability of their being speedily covered with bricks and mortar without any reservation of open spaces. About two years ago, however, Lord Egerton of Tatton, who is a large landowner in the district, presented the public, through the district council, with eleven acres of land to be used as recreation grounds. They are situated in convenient parts of the council's area, and with the Didsbury ground of between four and five acres in extent, which was purchased by the council for £3500, they constitute air spaces which will become increasingly valuable with the inevitable growth of the population. The Withington ground is rather more than five and a half acres, two other spaces are two acres and rather more than two and a half acres respectively, and there is another small plot. They are conveniently distributed and have been carefully laid out. No attempt has been made to convert them into public gardens, but iron railings have been placed round, trees have been planted,

Digitized by Google

and shelters erected, the present intention being to have them used as play-grounds for the young folks. The three principal grounds were formally opened by Lord Egerton on Saturday last.

The Coronership.

A special meeting of the city council was held yesterday to consider the appointment of a successor to the late Mr. Edward Herford, who has been coroner for very many years. For the last fourteen years the duties of the office have been performed by the deputy coroner, Mr. Smelt, a barrister. The state of things appears to have been somewhat anomalous. The coroner himself, being in failing health, some eighteen years ago appointed Mr. Smelt his deputy, and for fourteen years this gentleman has done the whole of the work, with, it must be acknowledged, satisfaction to the community. Mr. Herford has enjoyed the emoluments of the office with the dignity of ease and has paid Mr. Smelt by private arrangement with him. The corporation has chafed at times, but under the conditions of his appointment had no power to remove the city coroner. The election to the office is now, however, in the hands of the council, and by a local Act the corporation has the power, if it think fit, to pay the coroner by salary, as in the county, instead of by fees. The town-hall committee was instructed to consider and report as to what arrangement they would recommend as regards the office, and it was moved and carried that the appointment of coroner be postponed to the meeting on June 3rd. It was mentioned in the course of the discussion that "the average amount paid in medical fees for the last four years was £346, the average number of the inquests being 915 per year. The average sum received by the coroner during the last four years was £1220, and a total sum of £1821 16*s.* 10*d.* had been distributed on an average in each of the last fifteen years in coroner's fees and other expenses."

Manchester Medico-Ethical Association.

The Manchester Medico-Ethical Association devoted the last meeting to a discussion on the Registration of Nurses. The members present at the meeting—a large one—took a considerable amount of interest in the question, and after an animated discussion the following resolution was passed unanimously: "That any scheme for the legal registration of all nurses with a common standard of education is inimical to the interests of the public, the general body of nurses, and the medical profession, and that this meeting requests the committee to take steps to oppose any such scheme."

May 19th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Unqualified Medical Practice in the County of Durham and Some of its Results.

IN the very able report of the medical officer of health of the county of Durham Dr. Hill pointedly directs the attention of the county council to the number of uncertified deaths in the county palatine during the year 1895. The districts in which the practice is most prevalent are Spennymoor, Blaydon, Hetton, and portions of Chester-le-Street. It is due to the circumstance that so large a proportion of the medical practice is in the hands of unqualified persons. In Spennymoor last year 33 per cent. of the deaths were uncertified as the result of unqualified medical practice. Dr. Hill shows conclusively that this practice by unqualified men has a vicious effect upon the public health. "The proportion of deaths under one year and under five years to total deaths has been among those certified by registered medical practitioners only 34·4, and 49·1 per cent. respectively; the proportions among those deaths uncertified as a result of unqualified medical attendance were as high as 50·0 and 68·0 per cent. respectively. This excessive proportion of infant deaths in the practice of unqualified men is noticeable in all the districts where such practice prevails, so that it is certainly suggestive that many children die whose lives might have been saved had they received skilled medical attention." The object of the Infectious Diseases Notification Act is also defeated to a considerable extent by unqualified practitioners, for unqualified men are under no obligation to notify cases of infectious disease under the Act, and should they do so they are not entitled to any payment, consequently cases of infectious disease attended by these men are not reported to the sanitary authority. It is not creditable to the county that the percentage of uncertified deaths in it is twice as high as that for England and Wales. It ought not to be. It is the duty of the Durham County Council to bring the facts reported to them by Dr. Hill to the notice of the Local Government Board and of the General Medical Council, and to use its utmost endeavour to have a condition so disgraceful checked and put a stop to.

Labour Dispute on the North-East Coast.

Owing to a misunderstanding as to the interpretation of an agreement about wages a dispute has arisen between the men and the masters, and without any adequate attempt being made to arrange matters the men at Stockton-upon-Tees have recklessly struck work. In reply the masters on the Tees, Wear, and Tyne have given notice to 25 per cent. of the engineers to cease work in a fortnight. The men have now given power to their executive to bring out the 75 per cent. to whom notice has not yet been given by the masters. The masters propose arbitration. The men reply that their case is so good that arbitration is not necessary. The dispute involves only a matter of 6*d.* a week to 135 men—some £3 4*s.* a week—and for this paltry sum of money the whole district is not unlikely to be plunged into trouble, trade disorganised, and angry feelings excited, which will leave behind bitter feelings of clan animosity. How long, it is to be wondered, will this stupid, wicked system of settling disputes between capital and labour be tolerated? Mr. Knight, the able secretary of the Boiler-makers and Iron Shipbuilders Society, speaking upon the subject on a public occasion last November, expressed himself in the following terms: "I feel so strongly on this matter [strikes] that I would say without hesitation that if better means of settling differences cannot be obtained than by an awful strike I would advocate going to Government to pass a law to compel societies to adjust their differences by arbitration. As a last resort I would absolutely make arbitration compulsory." As a matter of fact, strikes and lock-outs are rare in the trades over which Mr. Knight has influence, and it is very much to be regretted that the affairs of the engineers are not managed in an equally judicious manner.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Edinburgh University.

AT a special meeting of the senatus of Edinburgh University the degree of LL.D. was conferred upon Sir J. Russell Reynolds by the Vice-Chancellor *in absentiâ*, and the usual diploma was forwarded to the recipient of the honour. The University field at Colinton Road is to be formally opened on Friday afternoon. His Grace the Lord High Commissioner, accompanied by the Marchioness of Tweeddale, is to take the leading part in the opening ceremony, after which there is to be a cricket match between the staff of the Royal Infirmary and the University eleven.

Death of Two Eminent Edinburgh Men.

Last week the death was recorded of two men eminent in different spheres of life who had studied and qualified at Edinburgh. The one was the Hon. Thomas Christie Smart, F.R.C.S. Edin., who died at Hobart, Tasmania. He was not only a prominent practitioner, but filled the mayoral chair and was elected to the Legislative Council. He was a public-spirited man, taking an active share in public work of various kinds. For eighteen years he was chairman of the Board of Management of the Hobart General Hospital, and did much to effect its efficient management. The other was Dr. Moxey, who died in Paris on his return journey from the Holy Land. He was a graduate in medicine of Edinburgh University and a Member of the Royal College of Physicians of London. In his early years he practised in England, but abandoned practice for elocution, and in that department was well known as Leo Ross. About eighteen years ago he came under the influence of evangelical teaching, and since that time has taken a part in evangelical work in Edinburgh and elsewhere. At several of the theological colleges in the country he held the position of lecturer on elocution. His death was quite unexpected and came as a great blow to his numerous friends in Scotland.

Dr. G. Hunter Mackenzie, Edinburgh, has been elected a Corresponding Member of the Société Française d'Otologie, de Laryngologie, et de Rhinologie.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

"Cyclopia."

THERE are two annual events in Dublin which have of late years assumed much prominence; one is the Horse Show, which, for an exhibition of its kind, is now unrivalled in Europe, and the other the May Carnival, Bazaar, or *fête* in connexion with the hospitals and medical charitable institutions. Both are held in the spacious grounds and buildings of the Royal Dublin Society at Ball's-bridge—a fact to which they certainly owe a large amount of their success. His Excellency the Lord Lieutenant for the time being is, as a matter of course, present. Lord Cadogan has recently shown a specially active interest in both undertakings, having received an influential deputation in connexion with horse breeding yesterday, while he has this afternoon (the 18th inst.) performed the inauguration ceremony at the formal opening of "Cyclopia," the monster bazaar in aid of the funds of the National Eye and Ear Infirmary. The hospitals of Dublin have benefited by such bazaars to the extent of many thousands of pounds, while some of the members of the medical staffs and committees have acquired wonderful skill in stimulating the generosity of the public. The first of the series of charitable carnivals was the memorable Masonic *fête*, which, besides being in itself a great success, served to rouse and excite the public taste for such displays. There is every reason to anticipate that "Cyclopia," which has just been opened, will outrival all its predecessors, for no trouble or expense has been spared towards that end. The preparations were begun more than a year ago and the attention of the public was first caught by advertisements in the daily journals of a competition and reward offered for the best suggestion as to a name for the coming festival. The title "Cyclopia" was then chosen from no less than 129 suggestions. Then came a poster competition with prizes of £10, the posters to become the property of the Bazaar Committee. These prize posters, of large dimensions, have been familiar to the streets here for many weeks. Moreover, the work on the committee was not, of course, confined to Dublin; ladies of social position and influence in each of the counties of Ireland were asked to become patronesses of stalls named after each county. The railway companies were induced to run excursions from all parts of Ireland. The prospects of this monster bazaar are good in every respect, but the entertainment is to a large extent an open-air one. There is, therefore, one matter which no skilled secretary can foresee—the Irish weather. During the next week it will go far to make or mar the success of the enterprise, and will certainly affect to the extent of several thousands of pounds the funds of the National Eye and Ear Infirmary.

Queen's College, Belfast.

The new lectureship on Ophthalmology has been filled by the appointment of Dr. W. A. McKeown, surgeon to the Ulster Eye, Ear, and Throat Hospital, a former distinguished student of the college. He is to give a three months' course of lectures during the winter session. The new pathological laboratory is practically finished, and Dr. Lorrain Smith has commenced a post-graduate course on Bacteriology, which is being well attended. The Dunville Trustees, who founded the chair of Physiology, have made a grant of £100 towards the fitting up of the new physiological laboratary. The arrangements for the new lectureship on Hygiene and Public Health are not quite completed, but the duties will probably be discharged by the professor of Chemistry and the public officer of health of the city of Belfast. It is also contemplated to establish a special course for those graduates who wish to read for the sanitary diploma of the Royal University. In addition to the Professor of Chemistry and the Public Officer of Health special courses will be given by the Professor of Geology and the Lecturer on Bacteriology. It was felt to be a distinct want that hitherto men preparing for this diploma could not get the necessary lectures and teaching in Belfast.

The Water-supply of Belfast.

Owing to the present dry and exceptionally hot weather 1,500,000 gallons of water extra are being used per day. Consequently the citizens have been urged to waste as little as possible, as with the continuance of this weather the stock of 208 days' supply might soon get exhausted. Some of the towns adjacent to Belfast have at present a very limited supply, and it is said that Bangor, a health resort much frequented by Belfast citizens, is in this condition.

Transfer of Lunatics rom Asylum to Workhouse at Belfast.

The everlasting question of the transfer of lunatics from the asylum to the Belfast workhouse came on again at an inquest held on May 18th in reference to the death of an old woman who was sent from the asylum on May 25th, 1895, to the lunatic department of the workhouse, where she died from exhaustion, at the age of seventy-five, on May 16th. This transfer of patients has been going on, it seems, for a period of fourteen years. The coroner having condemned very strongly the present system of transferring patients, the jury returned a verdict in which they condemned the system at present pursued of transferring patients from the asylum to the workhouse as being detrimental to those patients and unfair to the Belfast ratepayers; further, they stated that the transfer of the present case contributed to hastening the death of the deceased, and they requested the coroner to forward the evidence and verdict to the proper authorities. I understand that at the next meeting of the asylum governors an attempt will be made to come to some definite plan for arranging accommodation for lunatics.

The Battle of the Clubs at Cork.

Cork is threatened with the invasion of another medical club. A meeting was held last Friday in the Lecture Hall of the Young Men's Christian Association for the purpose of establishing a branch of the Independent Order of Foresters. "Dr." Oronhyateka, Supreme Chief Ranger, explained the objects of the Order, and in the course of his remarks mentioned that "he had been informed that there was a certain feeling among the physicians of Cork against the benefit society system, and that the medical men had banded themselves together with the object of trying to put down that system. Well, he believed that that matter would cure itself before very long. They had met such a feeling as that in Canada, but the Order became so strong that it was enabled to overcome any difficulty that arose, and he was sure that the same state of things would come to pass in Cork." *Nous verrons.* It is only necessary to recall the fact that some twelve months ago a very vigorous attempt was made to start a similar commercial speculation in Cork. The agent of the undertaking appeared before the medical association and explained that his company proposed insuring members, sending out touters, charging a certain sum for medical attendance and deducting a percentage to cover the cost of advertising and other expenses. Whilst impressing on the association that he was making them a splendid offer he informed them that whether they accepted it or not a project so pregnant with good for the public at large was bound to be started at once. But so chilling was the reception he got from the medical association that his beneficent designs have not so far assumed a practical shape. Despite the oratorical thunderings of "Dr." Oronhyateka his Order in Cork is destined to share a similar fate. One sentence in his speech was such a sparkling gem that it were a pity not to spread its effulgence in the medical world. "Perhaps," quoth "the doctor," "one of the greatest privileges of the Order was medical attendance practically free of charge." It is sincerely to be hoped that "Dr." Oronhyateka, imbued with the well-known American contempt for "the almighty dollar," gives his own services to the Independent Order on equally easy terms. "Do as you would wish to be done by" is a well-known saying; and as two clergymen from Belfast presided at the meeting with "the doctor," one as High Chief Ranger of Ireland and the other as High Vice-Chief Ranger, it may not be amiss to mention that there is an equally well-known text—"The labourer is worthy of his hire."

May 18th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Jenner Commemoration.

THE centenary of Jenner's first vaccination has been impressively celebrated in Berlin. Articles on his life and his work were published by all the leading medical and lay journals, the *Deutsche Medicinische Wochenschrift* having a special Jenner number devoted entirely to vaccination

Digitized by Google

matters and containing a portrait of Jenner, a biography of him by Dr. Pagel, a historical essay on Variolation by Dr. Behrend, articles on Vaccination in the German Army by Staff-Surgeon Dr. Wernicke, on the Arguments of the Anti-vaccinationists by Dr. Köhler, on Small-pox Mortality in Prussia by Dr. Heymann, and on Sterilised Instruments for Vaccination by Dr. Witte. A centennial exhibition has also been formed consisting of portraits of Jenner and other notable supporters of vaccination, of vaccination instruments past and present, of statistical tables, of anti-vaccinationist pamphlets, &c. On May 14th there was a meeting in the town hall presided over by Professor Virchow and attended by a very distinguished assembly, including the Minister of Public Instruction, the Director of the Army Medical Department, the Rector of the University, representatives of the municipal council, the medical corporations, and a large number of medical men. After Professor Virchow's inaugural address Professor Gerhardt gave an account of Jenner's work. He pointed out that while epidemic diseases, such as plague or typhoid fever, were suppressed or at least diminished by hygienic improvements small-pox, on the other hand, was subdued, not by the gradual progress of scientific knowledge, but by the genius of a single man. Jenner, it is true, had predecessors. Variolation, or inoculation with small-pox virus, which was introduced by Lady Mary Wortley Montagu, was a step in advance; but although it diminished the mortality it unfortunately propagated the disease. To understand how a country surgeon succeeded in making one of the most important discoveries of modern medicine it is necessary to bear in mind that he was so proficient a naturalist that the great explorer, Captain James Cook, when about to make the second of his voyages of discovery, offered to take Jenner with him. He was also a man of indomitable energy, which enabled him to triumph over obstacles and opposition. Those who were assembled on the present occasion for the purpose of doing honour to Jenner's memory might confidently expect that posterity a hundred years hence would not less freely acknowledge their indebtedness to his discovery. After the conclusion of Professor Gerhardt's speech addresses were delivered on behalf of the town council by Dr. Strassmann, who is a member of the council, and by Dr. Kruse, a medical member of the German Parliament; the proceedings then terminated. At the same hour the anti-vaccinationists held a meeting in commemoration of Jenner's "victims," which was opened by a funeral march, and after several speeches a resolution was passed demanding the abolition of compulsory vaccination, while anti-vaccinationist pamphlets were distributed both inside and outside the building and in the streets.

Leprosy in Eastern Prussia.

Leprosy is very rare in Germany in modern times. It seems to have disappeared since the sixteenth century, and the few cases which have been observed occurred in strangers coming from other countries where the disease was endemic. The public and the medical profession have, therefore, been much surprised to learn that in 1889 several cases of leprosy were observed in the district of Memel in Eastern Prussia, near the Russian frontier. The nearest centre of leprosy in Russia was about one hundred English miles from Memel, and contagion seemed, therefore, rather unlikely. The disease, however, slowly increased, and has recently been investigated by Dr. Blaschko, a Berlin dermatologist, who visited the district for the express purpose, and has since his return given an account of his observations at a meeting of the Berlin Medical Society. He first spoke of the hygienic condition of the population, saying that the country people are almost exclusively Lithuanians, are very ill-fed, and are in the habit of consuming an enormous quantity of spirits. Their dwellings are very small, unhealthy, and not at all ventilated; domestic animals occupy the same apartment as the family. Medical men are very seldom consulted, the population being not the least afraid of illness, and Dr. Blaschko sometimes saw sick persons sleeping in the same bed with the healthy. The leprosy cases hitherto observed in the district are twenty-two in all, nine of whom are still alive; this is not a small proportion in a population of about 16,000 persons. All the patients were Lithuanians, living in three distinct villages round the town of Memel, and have been leprous for several years; Dr. Blaschko was informed that no new cases had happened during the last two years. In no instance had the illness been communicated from husband to wife or *vice versâ*, but sometimes the children of leprous parents became affected. A hereditary influence was quite uncertain, as the children developed the disease at a somewhat advanced age. Notwithstanding the total want of isolation and cleanliness the extension of the disease is slow, the great majority of the people being apparently insusceptible. The medical men of Memel are of opinion that the disease is not due to infection, but is caused by the condition of the soil and by the food, which almost exclusively consists of fish. These causes are, however, not sufficient, as other localities where the same conditions exist are exempt. According to Dr. Blaschko the disease has been imported from Russia; for although the principal Russian centres of leprosy are somewhat distant from the frontier sporadic cases are found in nearer places which are in constant trading communication with the adjoining parts of Germany. He thinks that energetic measures should be taken to avoid the possibility of extension, and he suggests that a Government commission composed of dermatologists and hygienists should be sent to Memel in order to search for cases which may have been overlooked, while Russian immigrants should be most carefully observed. A gaol-like isolation, which was the rule in former times, is quite unnecessary, but the patients should be received in a special institution in the country where they may live apart from the healthy population. Dr. Blaschko closed his address by saying that the example of Russia, where 500 patients live in each of the provinces of Livonia and Kurland, should induce the German Government to keep a watchful eye on the endangered districts. Dr. Wassermann, of the Imperial Health Office, said that the Government intends to receive the lepers partly in the University Hospital of Königsberg, in Eastern Prussia, and partly in Professor Koch's hospital for infectious diseases in Berlin. If the malady were to become more widely spread a special hospital, as suggested by Dr. Blaschko, would be erected in the district of Memel.

May 19th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Supply of Quinine to Malarious Districts.

IN THE LANCET of Dec. 14th and 21st of last year I summarised and commented on the Bill introduced by the late Government for the supply of quinine to those malarious districts in which the chemist and druggist or the local dispensary are unknown. The present Government has adopted the Bill, with, however, what I cannot help thinking to be an unfortunate modification. Signor Boselli, its original author, was careful in the preamble of the Bill to disclaim all intention of creating in quinine, as in tobacco, a State monopoly. He was simply legislating for exceptional circumstances—the annual death in Italy of 16,000 persons from malarial fever, the existence of 4000 communes in which quinine is not to be had, and the excessive price, as well as the adulteration, of the quinine in those malarious districts where the specific is really (or nominally) on sale. At best the measure could be no other than temporary, pending the reclamation of those waste lands where malaria is endemic and the consequent stamping out of the disease. His successor in office, Signor Branca, proposes, however, to convert the sale of quinine into a source of gain to the Treasury, thus departing from the purely humanitarian and provisional view of the measure taken by Signor Boselli. A very serious complication is thus introduced. The legitimate claims of chemists and druggists were not ignored by Signor Boselli, and clauses in protection of their rights were contemplated as the Bill passed through Committee. But the creation of a monopoly in quinine, as in salt and tobacco—a monopoly, however, conceived and carried out in the interests of the Revenue—means the negation of the principle on which alone the Bill in its original form was framed and introduced. The career of the Di Rudini Ministry has already been a stormy one. It may suffer actual shipwreck on a measure which must arouse a much more uncompromising opposition than its highly contentious predecessor.

Ptomaine Poisoning from the Consumption of Fish.

This is a frequent cause of illness, sometimes of actual death, in Italy. In the November of 1894, as commented on in THE LANCET at the time, an eminent Florentine professor, his mother, and his wife died after having dined on a "cefalo" (a fish that frequents the mouths of rivers), with

Digitized by Google

all the signs of poisoning from some cadaveric alkaloid contained in the food, while the son and the cook, who had also shared the meal, narrowly escaped with their lives. Some six months afterwards here in Rome a well-to-do farmer with his wife and four children nearly died from the same cause, a prompt use of the stomach-pump being just in time to arrest the severe intestinal pains and violent retching that followed the ingestion of the unsound fish, and now, on the 14th inst., at Naples a family of three had to be removed to the Ospedale di Loreto after dining on a "mureno" (a favourite fish with the Neapolitan poor), all of them afflicted with "atrocissimi dolori viscerali" (the most excruciating abdominal pains). They are now out of danger, but pending the bacteriological investigation of the residue of the fish and of the egesta from the stomach they are supposed, like the Florentine and Roman families aforesaid, to have been the victims of ptomaine poisoning. Generally speaking, the tourist world is safe from such risks, as the hotels and *pensions* it affects are careful to supply such food as shall not repel their *clientèle*; but once let the artistic or archæological enthusiast venture out of the beaten track and dine on what is put before him at the rustic *osteria* or seaside inn and he will be fortunate if he escapes without intestinal disturbance or worse. We seldom open a newspaper without reading of "famiglie avvelenate" (families poisoned) by the consumption of food which, in spite of sanitary censorship, is bought up from butchers and fishmongers by itinerant hawkers, who vend it in suburban villages or the obscurer quarters of large towns.

Professor Andrea Verga.

On Dec. 7th last THE LANCET contained a full obituary notice of this greatest of recent Italian alienists, and at Milan on Friday, the 15th inst., in the edifice of the Società di Patrocinio pei Poveri Pazzi (Society for the Protection of the Insane Poor), a bust was unveiled to his memory. The Società (which, like many other organisations of the same kind in the Alta Italia, is his special creation) was largely represented on the occasion, while the legislature in both its branches, the municipality, the Lombard Medical School, and the *élite* of Milanese life had all their delegates at the ceremony. Below the bust—a *chef d'œuvre* of Branca—runs the following inscription from the pen of the Senator Massarani: "Ad Andrea Verga—Senatore del Regno—Intelletto serenamente profondo di molta e varia coltura nutrito—Che scrivendo ed operando irraggiò di nova luce—Gli arcani e le ambagi dell'anatomia e della pazzia—La società di patrocinio pei pazzi poveri, quella Freniatrica—amici ed ammiratori—Questo ricordo, testimonianza d'affetto, riverenti posero." (To Andrea Verga, Senator of the Kingdom, an intellect serenely profound, nurtured on extensive and varied learning, who by his precept and his practice shed new light on the obscure and intricate developments of the anatomy and pathology of mental disease, the Society for the Protection of the Insane Poor, the Phreniatric Society, as well as his friends and admirers, have with due reverence, in token of their affection, placed this memorial). The speakers (among whom Dr. Tamburini, Professor of Medico-Psychology at Modena, was present) recapitulated effectively the great services of the deceased to alienist medicine; but, as previously observed in these columns, a selection from his many masterly monographs read before scientific and clinical societies would, if republished, form a not less enduring and worthy monument to his name.

May 18th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Hungarian Millennium Exhibition.

THIS exhibition was opened on May 2nd by the King of Hungary Francis Joseph I. and the Queen Elizabeth. The sky kept cloudy in the morning, but about noon the sun came out and favoured with his genial smile the splendour of the festivities. Budapest looked very bright indeed, every house being flagged with the national red white and green tricolour and ornamented with carpets of every colour and shade. The ornaments bore the interesting character of a mixture of Western taste with Oriental luxury. Especially the broad and straight Andrassy-street, which leads to the site of the exhibition, offered a splendid view to those who were fortunate enough to secure a place on one of the balconies or a seat on one of the tribunes. The *cortège royal* driving to the opening festivities, with its shiny uniforms and brilliant national garments, was a delight to the eye, and gave a certificate of the wealth and good taste of our "upper ten thousand." The exhibition, which will be of six months' duration, is to commemorate the thousand years of the settlement of Hungarians in Europe. An early Hungarian anonymous writer stated that it was the year 889 of the era in which the Hungarians on their way from Asia had taken possession of this country. But the "Section of History" of the Hungarian Academy of Sciences found this to be an unreliable date, and after careful investigations and a long debate declared the year 896 as such, of which it can be made historically quite certain that the Hungarians were in possession of their present country under their chief, "Arpad," who is rightly considered to be the founder of Hungary.

Millennium Congress of Hygiene and Medicine.

This will be held in Budapest in September next and will bear rather a national character, as it will chiefly embrace questions dealing with the local statistics of hygiene, the dwellings of the poor, medical clubs, medical aid associations, infectious diseases, gratuitous medical aid and the like, with special reference to the wants of the country.

Anti-diphtheritic Serum in the Stefania Hospital for Children.

Professor J. Bokai has treated 402 children suffering from diphtheria with antitoxic serum of German, French, and Hungarian make respectively. He noted a mortality of 22¼ per cent. In those cases which required operative measures the mortality rose to 44½ per cent., while in lighter cases it sank to 10½ per cent. Taken as a whole the mortality from diphtheria in Budapest attained in pre-antitoxic times an average of from 34 to 37 per cent., whilst in the days of serum treatment the mortality is 21 per cent. It is also to be noted that formerly only from 8·6 to 15·2 per cent. of the diseased escaped operative interference, while under serum treatment 26 per cent. of the cases did not require any operation for laryngeal obstruction. In 22 per cent. a more or less marked exanthema followed the injections, especially those which have been effected with Hungarian serum.

Obituary.

PROFESSOR GERMAIN SÉE.

OUR Paris correspondent has sent us the following obituary notice of Professor Germain Sée:—

On Wednesday, the 13th inst., there disappeared from the medical arena of Paris a well-known figure in the person of Germain Sée. Although still retaining his chair of Clinical Medicine at the Hôtel Dieu Dr. Sée has practically been *hors de combat* for the last two years, and his death, which occurred at his house in the Avenue Montaigne, was no surprise to his friends. Born on March 6th, 1818, at Ribeauvillé, in Alsace, of a Jewish stock, he pursued his preliminary education in the Lycée of Metz, and, migrating as usual to Paris, graduated as M.D. at this Faculty in 1846. Six years later he was appointed *médecin des hôpitaux*, and then began a series of extra-academical lectures on pathology which attracted great attention. In 1866 he was, thanks to the strong recommendation of the Empress Eugénie, appointed to succeed Trousseau in the chair of Therapeutics at the Faculty. As the new Professor was never a *Professeur-agrégé* his nomination raised quite a storm of protestation amongst the teaching staff of the Faculty. He was, however, elected by 13 votes out of 23; but his difficulties were not over, for the students "made it so hot" for him that the Dean had to interpose so as to allow him to continue his lectures in peace. Although unpopular his strong individuality as a teacher soon compelled respect. Unfortunately his materialistic views drew upon him the thunders of the ultramontaine party, which culminated in a stormy discussion in the Senate. This incident enabled him to pose as a martyr, and a revulsion of feeling gave him a popularity that would otherwise not have been his. In 1867 he succeeded Professor Monneret in the chair of Clinical Medicine at the Charité, and in the following

Digitized by Google

year he was elected a member of the Academy of Medicine. In the fatal year 1870 he was the chief actor in a consultation which, had his recommendations been acted upon, would most probably have had the effect of preventing the international struggle of that year. The deceased professor's version of the affair is as follows. The Emperor Napoleon being very ill, a consultation took place at the Tuileries on July 1st, 1870, the consultants being Nélaton, Ricord, Fauvel, Corvisart, and himself. Professor Sée was entrusted with the drawing up of the report, which Dr. Conneau, the Emperor's body physician, was to have had countersigned subsequently by Professor Sée's fellow-consultants. This historical document is still extant, signed only by Professor Sée, Dr. Conneau having, for reasons unknown, not followed his instructions as to the other signatures. Professor Sée's and his *confrères'* diagnosis was stone in the bladder. Dr. Conneau further omitted to communicate the contents of this report to the Empress. The report was seized, amongst other documents found by the agents of the Government of Sept. 4th, in Dr. Conneau's rooms, and published subsequently in the collection of State papers found in the Tuileries and elsewhere. It would thus appear that two and a half years before the death of the Emperor the French medical men had diagnosed the existence of a calculus, and advised direct exploration of the bladder, which only took place thirteen months later, when the deposed monarch was an exile in England. It is quite possible that had their advice been followed extraction would have been decided on and war, declared only a few days after the consultation, deferred or perhaps abandoned altogether. Professor Sée remained to the end of his days convinced that war would have been averted had this fatal secrecy not been maintained. In 1877 Professor Sée was summoned to Constantinople to attend the Sultan Mourad, but on his arrival he found the Commander of the Faithful deposed and replaced by a successor who was in no need of medical advice. As to the late Professor Sée's contributions to science, it is probable that, despite the extent and varied character of his labours, his name will be associated in history with the therapeutical applications of salicylate of sodium and antipyrin as anti-rheumatic and analgesic remedies respectively; of milk diet and later of lactose in the treatment of chronic Bright's disease; and of potassium iodide and pyridine against asthma. The following is a list of his works: "Les Effets du Seigle Ergoté sur le Cœur et la Circulation" (Thesis, 1846); "Mémoire sur la Chorée et les Maladies Nerveuses" (1850); "Leçons de Pathologie Expérimentale: du Sang et des Anémies" (1866); "Mémoire sur l'Asthme" (Dictionnaire de Jaccoud, tome i., 1866); "Diagnostic et Traitement des Maladies du Cœur" (lectures delivered at the Charité, 1874–77); "Traitement du Rheumatisme par le Salicylate de Soude" (Bulletin de l'Académie de Médecine, 1877); "Médecine Clinique" (seven volumes, the last in collaboration with Dr. Labadie-Lagrave). This encyclopædia was begun in 1884, the first tomes being on pulmonary diseases, at the head of which was placed *la phtisie bacillaire*. The 1885 volume treated of pneumonia, which was recognised as a parasitical disease. One of the succeeding volumes is on "Diet of the Healthy and the Sick" Then came a work on "Diseases of the Kidney," by Dr. Labadie-Lagrave, and finally one by Professor Sée on "Diseases of the Heart." Amongst the other publications due to the pen of this prolific writer are "Hypertrophie Cardiaque de Croissance" (Académie des Sciences, 1883); "Des Pneumonies Infectieuses et Parasitaires" (*ibid.*, 1884); "De la Dilatation Atonique de l'Estomac" (in collaboration with Dr. Mathieu, 1894); and "Epilepsie et Bromure" (1884). His works on experimental therapeutics are very numerous and comprise a Memoir on the Treatment of Asthma with Potassium Iodide and Ethyl Iodide (1878); Researches on Convallaria Majalis (1882); Discourse on the Treatment of Typhoid Fever by Quinine and Large Doses of Alcohol (Académie de Médecine, 1883); Treatment of Asthma with Pyridine; On Spartein Sulphate as a Cardiac Remedy; On the Physiological action of Cinchonamine Sulphate (Institut, 1885); and Treatment of all forms of Bronchitis by Terpine (Académie de Médecine, 1885). In 1888 he contributed several papers to the Academy of Medicine on Stomach Affections (hyperchloridia, atony, &c.), and on strophanthinine. In 1889 he wrote (Bulletin de l'Académie de Médecine) on the Treatment of Diabetes by Antipyrin, and in the same year on Lactose as a Diuretic, on Iodide of Potassium in Heart Diseases, and on the Prophylaxis of Tuberculosis. In 1890 several interesting memoirs appeared: "Action de la Caféine sur les Fonctions Motrices et Respiratoires" (Sée and Lapicque), "Pouvoir Antiseptique de quelques Couleurs d'Aniline, le Chloral Antipyrine, le Pneumocoque Lancéolé dans la Pneumonie Grippale" (Académie des Sciences), "Noix de Kola, and the Usage du Cannibis Indica dans le Traitement des Névroses et des Dyspepsies Gastriques" (Académie de Médecine). Since 1890 Professor Sée had worked at a great treatise on experimental therapeutics, which he hoped to publish in conjunction with several co-workers. A few notes on nucleine had been issued, but increasing infirmities took the upper hand and his work was done. The vast range of his clinical activity may be judged of by the preceding long list. He was very strong in bibliography, and was an insatiable devourer of all foreign works bearing upon new discoveries, which he received and adopted with an open mind. Conservative medicine was abhorrent to his progressive instincts, and he warmly welcomed any innovation that promised to shed light on obscure points in pathology. Thus he did not fear to announce his belief in the bacillary origin of valvular disease of the heart. Despite his somewhat overbearing manners, his large athletic figure and strong, determined physiognomy will be missed at the Hôtel Dieu, where his clinical lectures were delivered for many years past. The funeral took place on May 18th at Montmartre, the pall-bearers being MM. Gréard (Recteur de l'Académie), Brouardel (Dean of the Faculty of Medicine), Hervieux (President of the Academy of Medicine), Roussell (Senator and Member of the Institute), Debove (Professeur Faculté de Médecine), and Lévy (Member of the Institute). Speeches were delivered by Professor Debove and Professor Landouzy the latter of whom, speaking for the Academy of Medicine, recalled the fact that the deceased learnt to read and write unaided and became the apostle of therapeutics and pathology in his native country. Professor Sée was promoted Commander of the Legion of Honour in 1880.

THOMAS CHRISTIE SMART, F.R.C.S. EDIN,

EX-M.P. FOR HOBART, AND PRIVY COUNCILLOR, TASMANIAN GOVERNMENT.

COLONIAL papers to hand convey the regrettable news of the sudden death of the Hon. Thomas Christie Smart, F.R.C.S. Edin., at his residence, Hobart, Tasmania, on March 26th. The deceased gentleman, who was an elder brother of Dr. Andrew Smart of Edinburgh, was educated in that city, and after taking his degree he left Scotland for Australia. When he reached the Antipodes he resolved to make Tasmania his home, and for about half a century he has been one of her most honoured citizens. After acting as Government medical officer at Manx Island, Mr. Smart began practice in Hobart, where his professional skill and personal qualities speedily established him in popular favour. He was a public-spirited man and his interest in civil and political affairs was very keen. He filled the mayoral chair, and he was unanimously elected to a seat in the Legislative Council, and he became a member of the Giblin Administration. In all these capacities Mr. Smart displayed marked ability and untiring zeal. The present efficient condition of the Hobart General Hospital is mainly, if not entirely, due to his self-sacrificing efforts, he having acted as chairman for the long period of eighteen years. Mr. Smart was a typical Scotsman and a capable exponent of Scottish song and story. Warm-hearted and generous, he was a staunch friend to the poor and needy, and his death is universally deplored throughout the length and breadth of Tasmania.

HENRY O'NAGHTEN FRASER-LUCKIE, M.B. LOND.

ALL who knew Henry O'Naghten Fraser-Luckie will hear with a sense of personal loss that he died from phthisis on May 5th. The knowledge that death came as a happy release after many months of illness takes away some of the sting of sorrow. In December, 1894, he took the degree of M.B. Lond., and in March, 1895, he entered into partnership with Mr. Coomber at Fakenham in Norfolk. He had an attack of influenza about a month after starting his new practice, and a second attack before he had recovered from the first still further weakened him. A fresh cold started a pneumonic phthisis, affecting the whole of his left lung and the upper lobe of the right lung. Dr. Fraser-Luckie gave up his partnership and returned to London early in June. He gained ground for about two months, then began to get worse again, and in October went to Bordighera, but in December he developed tuberculous laryngitis. As he

Digitized by Google

was getting steadily worse he came home in February. He gradually sank and on Easter Monday developed a pneumothorax. His heart failing towards the end, he passed quietly away at 1.15 P.M. on Tuesday, May 5th. He was buried at noon in Wandsworth Cemetery on the 9th. Dr. Fraser-Luckie was educated at the International College at Isleworth. He entered St. Bartholomew's Hospital in 1884. The reasons for Dr. Fraser-Luckie's great popularity were not hard to discover. Gifted with a sunny nature, his cheery voice and merry laugh put everyone into a good temper at once. His sound common sense and powers of observation enabled him to tackle difficult problems both in his work and in his life with success. He was a sportsman of the purest type, always willing to give a beginner a hint or to do a friend a good turn. His fine physique and natural aptitude for sport made him a good football player, oarsman, swimmer, and boxer. His splendid pluck and kindly nature were very evident all through his long and trying illness. What a trial nine weary months in bed must have been to such an active man can readily be realised; but Dr. Fraser-Luckie never once complained, and when the end came he passed quietly away, leaving in the memory of his friends a blank which will never be filled.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent medical men are announced:—Dr. Finkelnburg, Extraordinary Professor of Hygiene in the University of Bonn.—Dr. F. Semal, who was President of the International Anthropological Congress at Brussels.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen passed the First Professional Examination in Anatomy and Physiology for the diploma of Fellow on Wednesday, May 13th:—

Ramon Horace Castellote, M.R.C.S. Eng., L.R.C.P. Lond., University College, London; Francis James Steward, M.R.C.S. Eng., L.R.C.P. Lond., Guy's Hospital; Vaughan Pendred, M.R.C.S. Eng., L.R.C.P. Lond., Durham University and Guy's Hospital; Edwin Claude Taylor, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University and Guy's Hospital; Neville Reginald Howse, M.R.C.S. Eng., L.R.C.P. Lond., London Hospital; Edward Hugh Edwards Stack, M.B., B.C. Camb., M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; Wallace Charles George Ashdowne, M.R.C.S. Eng., L.R.C.P. Lond., St. Mary's Hospital; and Arthur Ferguson MacCallan, Cambridge University and St. Mary's Hospital.

Eight gentlemen were referred back to their professional studies for six months.

Thursday, May 14th:—

Herbert Edwin Harris, M.B. Camb., M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital; William Henry Quicke, M.D. Brux., M.R.C.S. Eng., L.S.A. Lond., Surgeon-Major I.M.S., Westminster Hospital and King's College, London; Arthur Ruscombe Crane Parsons, King's College, London; John Alfred Barnes, St. Thomas's Hospital; Thomas Percival Barry, Guy's Hospital; Cyprian Royston Pike, London Hospital; and Ernest Edward Glynn, Cambridge University.

Nine gentlemen were referred back to their professional studies for six months.

Friday, May 15th:—

George Thomas James, M.R.C.S. Eng., L.R.C.P. Lond., Westminster Hospital; William Layard Griffiths, University College, London; George Haywood Herbert, London Hospital; Edred Moss Corner, Cambridge University and St. Thomas's Hospital; Alfred Henry Gedson, Cambridge University, Owens College, Manchester, and Guy's Hospital; Leonard Hugh McGavin, Guy's Hospital; and Sidney Maynard Smith, St. Mary's Hospital.

Nine gentlemen were referred back to their professional studies for six months.

Monday, May 18th:—

Arthur Robinson, M.B. Edin., M.R.C.S. Eng., Edinburgh University; Francis Barclay Willmer Phillips, M.B. Oxon., M.R.C.S. Eng., Philip Northcott Vellacott, M.R.C.S. Eng., L.R.C.P. Lond., Shaik Abdur Ruzzark, and Walter Henry Maxwell Telling, Guy's Hospital; Harold Shuttleworth Barwell, St. George's Hospital; Hugh Fitz Neville Hine, Middlesex Hospital; Frank Cole Madden, M.B. Melb., Melbourne University and St. Mary's Hospital; Arthur Martin-Leake, University College, London; and Irwin Walter William Hunter, Otago University, New Zealand, and London Hospital.

Ten gentlemen were referred back to their professional studies for six months.

Tuesday, May 19th:—

Frederic Victor Millward, M.B., B.C. Camb., M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital; Michishige Takayasu, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's Hospital; John William Geary Grant, M.R.C.S. Eng., L.R.C.P. Lond., St. Thomas's Hospital and Newcastle-on-Tyne College of Medicine; and Frederick Edward Walker, Guy's Hospital.

Eleven gentlemen were referred back to their professional studies for six months. One hundred and nineteen gentlemen presented themselves for this examination, of whom forty-nine passed and seventy were referred.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—The annual general meeting of this society will be held on Monday, June 1st, at 8 P.M., when, in addition to the usual business, Dr. Washbourn will read a paper on "Some Points in Connexion with the Bacteria of the Mouth," to be illustrated with lantern slides.

THE CITY OF LONDON TRUSS SOCIETY.—The eighty-ninth yearly dinner in aid of the funds of the City of London Truss Society was held on Tuesday evening last at the Albion Tavern, Aldersgate-street, under the presidency of the treasurer, Mr. John Norbury. The chairman, in proposing the toast of the evening, dwelt at length on the objects of the society, and announced donations to the amount of nearly £735.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. Henry R. Powell, L.R.C.P., L.R.C.S. Edin., has been presented by the members of the Anfield Conservative Club, Liverpool, with an illuminated address and portrait as a token of their esteem and for his valuable services to the club.—On leaving Warwick Dr. Guthrie Rankin was recently presented by his numerous friends and patients with an artistically designed pair of silver candelabra and other pieces of silver plate, besides many valuable presents from individual patients. He was also entertained at a farewell dinner by the members and friends of the Warwickshire Burns Club, presided over by Dr. George Wilson, and on that occasion was presented with a handsome album containing an illuminated address and numerous photographs of the other presidents and friends of the club.—Mr. Fox T. Jackson, L.R.C.P. Lond., M.R.C.S. Eng., has been the recipient from members of the Huyton section of the St. John Ambulance Association, Liverpool Brigade, of a clinical thermometer in a silver case.

CLINICAL SOCIETY OF LONDON.—The annual meeting will be held this (Friday) evening at 8.30 P.M. The following is a list of the officers and members of Council recommended by the Council for election for the year 1896-7:—President: Thomas Buzzard. Vice-Presidents: Thomas Barlow, Frederick Taylor, Thomas T. Whipham, William Henry Bennett, Rickman John Godlee, and William J. Walsham. Treasurer: William Miller Ord. Council: W. H. Allchin, W. P. Herringham, Constantine Holman, Patrick Manson, Sidney Martin, F. W. Mott, F. G. Penrose, Seymour J. Sharkey, E. Markham Skerritt, W. Hale White, Dawson Williams, W. Bruce Clarke, A. Pearce Gould, C. R. B. Keetley, C. B. Lockwood, Rushton Parker, Bilton Pollard, A. Q. Silcock, W. G. Spencer, and J. Bland Sutton. Honorary Secretaries: G. H. Makins and J. Kingston Fowler. Trustees: Christopher Heath, William Miller Ord, and J. Burdon Sanderson.

THE WHITSUNTIDE HOLIDAYS.—Great Eastern Railway.—Whitsuntide on the Continent.—For the holidays cheap return tickets will be issued to Scheveningen (the Dutch Brighton) *viâ* Harwich and the Hook of Holland. Passengers will leave London or the northern and midland counties on Friday, May 22nd, and crossing by a special steamer will reach Scheveningen in time for breakfast next morning. These tickets will be available to return any day up to and including May 30th. Return tickets at single fares will be issued to Berlin for the Exhibition on May 22nd. Cheap tickets will also be issued to Budapest for the Millennial Exhibition. Short Belgian tours, including Brussels (for Waterloo), the Ardennes, and the picturesque Flemish cities, have been arranged *viâ* the Harwich-Antwerp route.—The General Steam Navigation Company's fast passenger steamers *Peregrine* and *Seamew* will leave Harwich on May 20th and 23rd for Hamburg, returning May 24th and 27th.—The London and North-Western Company announce that the ticket offices at Euston, Broad-street, Kensington, and Willesden Junction will be open throughout the day until Whit-Monday, May 25th, so that passengers wishing to obtain tickets for any destination on the London and North-Western Railway can do so at any time of the day prior to the starting of the trains.

Digitized by Google

ROYAL METEOROLOGICAL SOCIETY.—The monthly meeting of this society was held on Wednesday evening, the 20th inst., at the Institution of Civil Engineers, Great George-street, Westminster, Mr. E. Mawley, F.R.H.S., President, in the chair. An interesting collection of photographs of clouds sent to the society by Mr. H. C. Russell, F.R.S., of the Sydney observatory, was exhibited.

A DINNER in aid of the funds of the National Orthopædic Hospital was held on May 14th in the Whitehall Rooms of the Hôtel Métropole. The President, the Duke of Marlborough, who was accompanied by the Duchess, took the chair, and in proposing the toast of the evening, "The Prosperity of the Hospital," said that a deficit of £1600 had to be cleared off. Donations to the amount of £681 were announced.

THE PHARMACEUTICAL SOCIETY.—The annual dinner of the members of the Pharmaceutical Society of Great Britain was held on Tuesday night last at the King's Hall, Holborn Restaurant, Mr. M. Carteighe, the President of the society, being in the chair. Mr. J. Harrison proposed "The Medical Profession," and Mr. Christopher Heath, President of the Royal College of Surgeons of England, in response, acknowledged the indebtedness of the medical profession to the Pharmaceutical Society.

MUNIFICENT GIFT TO THE JENNY LIND INFIRMARY FOR SICK CHILDREN, NORWICH.—Mr. J. J. Colman has presented to the Governors of the Jenny Lind Infirmary three and a half acres of freehold land as a site for a new infirmary. The land has been purchased from the Ecclesiastical Commissioners and has been presented to the trustees of the infirmary as a memorial to the late Mrs. Colman, who always took the warmest interest in the institution. Donations for the building fund are urgently needed in order that the erection of the new hospital may be carried out forthwith.

DIPHTHERIA IN LONDON.—The data for the four-weekly period ended April 18th show a diminution in the amount of diphtheria in London, the cases notified during each period of four weeks in the present year up to the date just named having been as follows:—To Jan. 25th, 988 cases; to Feb. 22nd, 1054 cases; to March 21st, 1009 cases; and to April 18th, 785 cases. The deaths during each week of the fortnight ended with Saturday, May 2nd, were only 41 and 36 respectively. In the week ended on May 9th the fatal cases in London increased again to 41, and were 10 in excess of the corrected weekly average, including 9 residents in the parish of Islington and 3 each in Hammersmith and Lambeth sanitary areas. There was only one death in an infant under one year of age, but 25 occurred in young children in the next four years of life. The admissions to hospital were 101, and the patients remaining under treatment on May 9th reached a total of 707. In Greater London the deaths registered were as many as 14, and no fewer than 9 of these belonged to the West Ham district.

THE ROYAL SOUTH HANTS INFIRMARY.—If any reason were needed to prove the necessity for the scheme which the governors of this infirmary at Southampton have in hand, it is afforded by a resolution recently passed by the medical staff and which was read at a public meeting on May 14th. The staff wished to record their "opinion that for many years past numerous outbreaks of preventable disease had occurred among the patients, and more especially among the resident staff, nurses, and servants of the institution, and that these outbreaks are directly attributable to the insanitary condition of the hospital. We are of opinion that this insanitary condition is largely due to the faulty structural arrangements of the buildings, and that nothing less than a reconstruction of the greater part of the hospital can render the institution suitable for the successful treatment of disease. It is well known that the diseases alluded to above are almost unknown in modern hospitals built in accordance with the now well-recognised principles of hospital construction." The scheme has been in hand for some time, and it is now proposed to erect additions at the rear of the present infirmary, adopting the circular system. The difficulty in remedying existing defects lies in the fact that the infirmary is of different dates and is practically a series of additions to the original nucleus. Only the large Eyre Crabbe wing is said to be thoroughly satisfactory. The cost of the amended scheme is put at £19,000, and of this, although an appeal is only just issued, the sum of about £5800 is promised.

CAMBRIDGE UNIVERSITY: EXAMINATIONS FOR MEDICAL AND SURGICAL DEGREES, EASTER TERM, 1896.—The certificates of candidates for the First and Second M.B. Examinations, accompanied by their postal addresses, must be sent to the registrary on or before Wednesday, June 3rd, for the First Parts, and on or before Friday, June 5th, for the Second Parts.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held at "Stanley's," Lavender-hill, S.W., on the 13th inst., Dr. Gilbert Richardson being in the chair. A paper was read by Dr. Amand Routh on Hæmorrhage during the Early Months of Pregnancy, which appeared in THE LANCET of May 16th. A discussion followed, in which Mr. Benjamin Duke, Dr. Caldwell Smith, Mr. John Gay, Surgeon-Major Mark Robinson, Dr. Hillstead, Mr. T. A. I. Howell, and others took part. Dr. Amand Routh having replied, a hearty vote of thanks was accorded to him for his paper.

WALSALL MEDICAL SOCIETY.—The first meeting of the members of the newly-formed Walsall Medical Society was held in the Committee Room of the Walsall and District Hospital on Friday, May 8th. There was a good attendance of members. The President (Mr. Phillips), after pointing out the immediate objects in forming the society, gave a very interesting address based upon a comparison between the Medical Directory of 1779 and that of the present year. He drew attention to the modes of treatment in vogue at that time and showed how many of these were being rediscovered and presented to us in a more modern form. After a vote of thanks the meeting terminated.

OXFORD UNIVERSITY: EXAMINATIONS FOR MEDICAL AND SURGICAL DEGREES, TRINITY TERM, 1896.—The examinations for the degree of Bachelor of Medicine will commence in the Examination Schools on Monday, June 22nd, 1896. The Secretary to the Boards of Faculties will receive the names of candidates—either by letter or from the candidates in person—at his office in the Clarendon-building, Broad-street, at any time not later than 10.30 A.M. on Monday, June 8th, 1896. The examination for the degree of Master in Surgery will commence on Monday, June 29th. The names of candidates must be sent to the Clarendon-building, Broad-street, at any time not later than 10.30 A.M. on Monday, June 15th.

THE DIFFUSION OF SMALL-POX.—For the weeks ending May 9th there was a clean sheet so far as regards registered deaths from small-pox in the thirty-three great towns tabulated by the Registrar-General. The small-pox admissions to hospital in London were only 5, the cases admitted in the preceding three weeks having been 4, 8, and 3 respectively, and 15 patients remained under treatment. Small-pox seems to have been recently spreading in and around Wycombe, traceable in the first instance to infection from rags brought from Gloucester. Mr. Carlile, M.P., has given notice of a question to be addressed to the President of the Local Government Board having reference to the matter, in which he makes mention of the occurrence of 15 cases in the district, and propounds the subject of disinfection of rags before they reach the sorters' hands. The matter of disinfection would be one of great difficulty and would also involve no small expense. With a general enforcement of the Vaccination Acts among the workers in paper mills there should be no necessity for disinfection of rags in so far as small-pox is concerned, and other diseases spread by the medium of rags seem to be few in number and such outbreaks to be of rare occurrence. As a matter of fact the Acts have been in abeyance in the Wycombe Union for some years, so that it is not only in the mills that there is danger of dissemination of small-pox when once introduced. In Gloucester there is no longer that rush for vaccination and revaccination which set in a month ago, and the guardians have been summoning some defaulters before the magistrates, but they have met with only scant success. We read of parents summoned in respect of dead children, of wrong individuals named in the summons, and of parents having had their children vaccinated prior to appearance in court, and of the guardians having omitted to direct their vaccination officer to proceed against defaulters under their seal. In the week ended May 7th the new cases of small-pox reported to the town council numbered 81, the totals in successive weeks having steadily fallen, the numbers having been 211, 201, 168, and 131

Digitized by Google

immediately prior thereto. The patients admitted to hospital were 23 and those discharged 15, whilst 16 deaths were recorded, of which 10 occurred in home-treated patients. The Registrar-General, in respect of the week ended two days later—namely, on May 9th—gives the registered deaths from the disease occurring in residents within the municipal borough as 24, and one death without the city boundary. The total cases heard of up to the end of last week amounted to 1700. The patients in hospital at the close of the week were within one or two of 300. Further cases of small-pox are reported from Heywood, where there are said to be 3000 unvaccinated children. The Clayton Hospital, near Manchester, has had to be reopened on account of the occurrence of a case of small-pox in the city.

QUEEN'S COLLEGE, BELFAST.—The following is the prize-list at the close of the winter medical session of the Medical Faculty:—Anatomy—Seniors: A. B. M'Master; Junior Division A: J. E. Clements and David M'Mordie; Junior Division B: Annie H. Crawford and J. W. West. Practical Anatomy—Seniors: A. B. M'Master; Second Year: Annie H. Crawford, W. M. Hunter, and Alexandrina C. Hunter (equal); First Year: David M'Mordie and J. E. Clements. Physiology and Histology—Senior Division: R. A. L. Graham and David M'Cay; Junior Division: W. M. Hunter, Robert Hilton, and W. D. Hamil (equal). Practical Physiology and Histology—R. A. L. Graham, G. H. Grills, and A. B. M'Master. Medicine—David M'Cay and Wm. Simpson. Surgery—Second Year: O. E. M'Cutcheon, B. A., and R. W. G. Stewart; First Year: C. E. M'Dade, B.A., David M'Cay, and A. B. M'Master. Materia Medica and Therapeutics—Hugh Donnelly. Midwifery, Gynæcology, and Diseases of Children—R. W. G. Stewart, O. E. M'Cutcheon, B.A., David Fleck, and G. A. Hicks. Practical Chemistry (Arts and Medicine)—Junior Division: Eleanor R. Sproule, J. A. Smith, S. S. Miskelly, and Robert Mathewson. Zoology (Arts and Medicine)—Senior: W. D. Hamill; Junior: A. G. Heron, J. C. Rankin, David M'Mordie, and A. L. Black.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Introduction of Sir William Priestley.

AT the commencement of proceedings on Thursday, May 14th, Sir William Priestley was introduced to the House on his election as the representative of Edinburgh and St. Andrews Universities by Mr. Curzon, Under Secretary of State for Foreign Affairs, and Sir John Mowbray, the member for the University of Oxford.

Pauper Aliens.

Mr. Ritchie, President of the Board of Trade, has made it known that he entertains little hope of being able to introduce a Bill dealing with the immigration of pauper aliens during the present session of Parliament.

London Water-supply.

The Bill of the Government to create a Water Board for the Metropolitan Counties passed the Committee stage in the House of Lords on Monday, May 18th, and while it was altered in very few respects it received several additions. For instance, a clause was introduced enabling county authorities to make arrangements of their own for a water supply, and on doing so to withdraw from the Water Board. This was done on the motion of the Government, while on the motion of Earl Cowper another clause was inserted providing that nothing in the Bill shall affect the right of a metropolitan county to be heard before a committee of Parliament in opposition to a Bill promoted by the Water Board.

HOUSE OF COMMONS.

MONDAY, MAY 18TH.

Court-house Accommodation.

Mr. Pickersgill asked the Secretary of State for the Home Department whether any steps had recently been taken to complete the objects of the Home Office Committee of 1887, appointed to inquire into the accommodation provided for prisoners in the court-houses of England and Wales, and how many of the places of detention in these court-houses still continue in a defective condition.—Sir Matthew White Ridley replied. It was stated in 1891 by the Home Secretary of the day, in reply to a similar question, that as a result of the action taken by the Home Office on the report of the committee the accommodation at court-houses for prisoners brought up for trial might at some 150 places be regarded as satisfactory. I am happy to be able to say that since that date a satisfactory result has been arrived at also in the majority of the forty or fifty cases in regard to which correspondence was then going on. In a very few cases the local authority has failed to comply with the requirements of the Secretary of State, and in default of fresh legislation I am unable to compel them. I may add that the matter is one to which attention is paid by the inspectors of prisons and prison governors, who report annually and call attention to any defect requiring remedy.

Registration in Belfast.

Mr. Gerald Balfour said, in reply to Mr. Young, that the Registrar-General had again carefully considered the question of the sufficiency of the existing arrangements for the registration of births and deaths and he had suggested to him (Mr. Balfour) the desirability of holding a public inquiry at which all persons locally interested might appear either personally or by solicitors. In this way the facts could be more fully investigated and he had authorised the Registrar-General to hold the inquiry in Belfast as soon as could be conveniently arranged.

The New Tuberculosis Commission.

Mr. T. W. Russell, Parliamentary Secretary to the Local Government Board, announced, in reply to questions by Dr. Farquharson and Mr. Field, that he could not hold out any expectation that a measure would be brought in this year with regard to tuberculosis, but the President of the Local Government Board hoped to be able to name the Royal Commissioners and the order of their reference shortly after Whitsuntide.

The Pleuro-pneumonia Account.

Mr. Walter Long, President of the Board of Agriculture, said, in reply to a question, that the total payments out of the Cattle Pleuro-pneumonia Account for Great Britain in 1895-96 were £216,769, while the receipts were £25,000 from the Exchequer, £165,000 from the Local Taxation Account, and £27,223 from the sale of carcases, &c. The balance to the credit of the account at the end of the year 1895-96 was £887, and at the present moment it was £15,373.

TUESDAY, MAY 19TH.

Treatment of Verminous Persons.

Mr. Hazell asked the Secretary to the Local Government Board whether the local sanitary authorities and the guardians had already the power to expend money upon the gratuitous cleansing of any verminous persons who might apply to them without treating such persons as paupers or detaining them longer than was necessary for the purpose, or whether any expenditure for this object would be surcharged against the local authorities by the Government auditors.—Mr. T. W. Russell said he was advised that boards of guardians had no legal authority for the expenditure of the rates for the purposes referred to in the question and that urban and rural district councils were in the same position in this matter. With regard to the second question he could only state that it was the duty of an auditor to disallow any expenditure by a local authority whose accounts were subject to audit by him which in his opinion was illegal.

Vaccination Prosecutions.

Mr. Thomas Bayley asked the President of the Local Government Board whether he was aware that a fifth summons had been taken out against William Guest of Quinton by the Stourbridge guardians for refusing to vaccinate, and that the said William Guest had been imprisoned several times under the Vaccination Acts, and on one occasion was sentenced to hard labour contrary to law; and whether he would advise the guardians that the case came within the letter to the Evesham guardians and should not be prosecuted?—Mr. Chaplin replied: I have no reason to doubt the accuracy of the statement in the question as to the proceedings which have been instituted against William Guest for the non-vaccination of his children. I have directed that a copy of the Evesham letter should be forwarded to the guardians of the Stourbridge Union.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"THE POISON OF THE PRIMULA."

To the Editors of THE LANCET.

SIRS,—Permit me to report a case of primula poisoning which came under my care last summer. The patient consulted me concerning an eruption on her face and hands of an eczematous nature and which I pronounced eczema. It did not yield to treatment, and I began to suspect that she might be suffering from contact with some poisonous plant—such as the poison ivy—as the eruption resembled that caused by the Rhus radicans and Virginia creeper, but was assured that such was not the case. She recovered perfectly when the cold weather came on, and she now remembers that the trouble followed handling the primula. Upon making further inquiries I am informed of three cases, all ladies, in which handling the plants causes a painful burning itching, with an eruption of small vesicles having an inflamed base, evidently more eczematous than erysipelatous in character. I am inclined to think primula poisoning rather common.

I am, Sirs, yours truly,

Port Hope, Ontario, April 23rd, 1896. J. W. CLEMESHA.

Veritas will find full information respecting the Army Medical Service in our Students' Number, published on Sept. 7th, 1895.

A MEDICAL BOTANIST.

THE following is a perfectly true story:—

A medical man was examining a rash upon a patient's back.

M.D.: "Is this rash growing?"

Patient: "Yes, of course it's growing."

M.D.: "Why do you say 'of course'?"

Patient: "'Cos it's a plant."

M.D.: "Yes, it is a plant; but how did you know that?"

Patient: "Why, they told me at the 'orspital it was a 'sycamore.'"

M.D.: "A sycamore!"

Patient: "Yes, they said as 'ow it was a 'variety of sycamore.'"

The rash was that of pityriasis versicolor.

X. Y. Z. is informed that we neither prescribe nor recommend individual practitioners. His ordinary medical attendant should be able to give him the names of medical men who make a special study of such matters.

Observer.—1. Our correspondent is right in his estimate of the part played by muscle. It is notorious that muscular power has but little to do with the force of the stroke, the pace with which the ball travels is almost entirely dependent upon the accuracy with which the stroke has been timed. 2. The family medical man would be able to decide whether the boy is too delicate to play, but cricket at public schools is a well-managed sport. The risks of catching cold or of compulsory play lasting for too long a time are very small, and we think that the boy must be very delicate or organically unfit to go to school at all if he cannot take part in the game.

Inquirer.—Dr. Barry's qualifications were obtained in Edinburgh; but the members of the Army Medical Service were not necessarily doubly qualified in those days.

NOVEL USES FOR THE "X" RAYS.

THE new photography is fast becoming a useful adjunct to every-day life and promises to be serviceable in many fields besides that of medicine. Experiments have been made in France, attended, we believe, with some success, with a view to ascertaining the contents of an infernal machine. With packages made to explode upon their being opened by the recipient the "x" rays should perform a useful *rôle*, but where the machine is timed to explode the new process will, we fear, be of little use. Among the newest uses of the "x" rays is the detection of imitation gems. From an illustrated article in *La Nature* it would appear that the new photography is likely to act the part of an important detective in this direction.

Practitioner.—The necessary competition taking place in an overcrowded profession accounts for many annoying incidents. We do not see that there has been any breach of professional etiquette.

THE MERE MALE.

To the Editors of THE LANCET.

SIRS,—Being up in London for a few days' holiday and being anxious to see as much hospital practice as possible during my stay, I thought that I should like to attend the practice of the New Hospital for Women in the Euston-road. Seeing in THE LANCET that the out-patients were attended at 2 o'clock every day I went there last Wednesday afternoon and saw the secretary, and told her that I was a medical practitioner and wished to see the out-patients. She said the hospital was conducted by female practitioners only, and no medical man could be admitted as the patients would not like it. I have visited a large number of hospitals at different times and never before been refused admission. How is it that a notice is put in the medical journals advertising the hours at which out-patients are seen and operations performed and yet it is impossible for a medical man to take advantage of it?

I am, Sirs, yours truly,

Boston, May 19th, 1896. ED. B. RECKITT, M.D.

*** The limitations laid down by the secretary to Dr. Reckitt have not been brought to our notice by the hospital. Our correspondent will probably be neither surprised nor, under the circumstances, displeased to read in our present issue that the Pathological Society of London has refused by a large majority to admit women members.—ED. L.

A. H. C.—We cannot endorse our correspondent's assignment of evil motive to the action of the late tenant. He is, we presume, in possession of information warranting him in making the assumption. It is usual for a medical man when leaving the house where his patients have been in the habit of seeing him to indicate where he may be seen for the future. The size of the notice board and the amount of details given upon it must be left to individual taste, as must also the length of time during which the board is kept up.

AT AN INQUEST.

WE extract the following paragraph from the *Daily Mail* of May 16th. Surely the coroner did not really allow this scene to take place.

"Yesterday, during the holding of an inquest at Shoreditch, a doctor witness said he could not say the actual cause of death.—The coroner: Then go and make a post-mortem examination.—On his return the doctor said there was congestion of the lungs, but he could not say whether that or suffocation was the cause of death.—A juror: I don't think the doctor knows what he is about.—The doctor: Oh, yes, I do.—Another juror: I don't think so. I've been in the Army Medical Corps and know a little.—The doctor: And I've been an army surgeon.—Another juror: Are you a doctor?—The doctor (indignantly): Most decidedly.—The foreman: Well, you are a funny one. (Laughter.)—A juror: I don't think he knows where he are. (Renewed laughter.)—The coroner said that the doctor was a duly qualified man and was giving the jury his opinion.—Eventually the doctor said that the cause of death was natural.—A juror: At last! (Laughter.)"

M. D. E.—It is, of course, impossible for us to decide upon the merits of the diagnosis not having seen the case, but accepting our correspondent's account of the signs and symptoms there can be no doubt that he was correct. The second medical man appears to us to have not been well advised in his conduct of the matter. It was not his fault that his experience in this particular direction was small, but it is to be regretted that on so small an experience he should have founded a direct contradiction to his senior and should not have made a representation to the parents of the patient that a third opinion was necessary to decide between the opposing diagnoses.

Final M.B.—Our correspondent's time is too short if we are to understand that he is intending to commence reading now. Erichsen's Surgery, Taylor's or Osler's Medicine, Luff's Jurisprudence, Green's Pathology, Mitchell Bruce's Materia Medica, and Lusk's Midwifery are recommended, but each might be supplemented with advantage by other text-books.

"A NEW CIGARETTE" (*sic*).

MESSRS. DRAPKIN AND MILLHOFF, of 27, Commercial-street, E., send us some specimens of "a new cigarette" which is said to be free from irritating properties. The cigarettes, while cool-smoking and devoid of pungency, are, judging from the pleasant aromatic character of the smoke, composed of selected leaf of the Dubec type. They do not strike us as possessing any marked advantage over many well-known brands, the good quality of which is probably dependent also upon the selection of superior leaf.

L. B. S.—We see nothing offensive whatever in the circular. It is stated at the top to be "Addressed to Medical Practitioners" only, and the process is so clearly auxiliary in many ways to the duties of the practitioner that it is right that facilities for its application should be placed within his reach.

SOME QUERIES.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly answer the following questions?—What proportions of liniments of aconite, belladonna, and chloroform are most useful to make the A.B.C. liniment? How is it best applied and in what cases most suitable? Which is the most useful chloroform inhaler and which the best chloroform drop-bottle for a general practitioner? I am, Sirs, yours truly,

May 18th, 1896. SURGEON.

WE have received from Messrs. Reynolds and Branson a hammer which should recommend itself to practical pathologists with highly endowed sensibilities. It is for use in making a necropsy, and has a head protected with a mass of resilient indiarubber so that strokes upon the chisel will be silent.

Drugs.—No medical right would be thereby infringed.

INFECTION AND FEAR.

WE extract the following from an American journal:—

"A story has been told at times during the past ten years in this city of a resident who, imagining he was ill, went to bed, and when told by the physician who had been summoned to attend him that nothing was the matter with him replied that he was sick, he knew he was sick, and would be dead in less than a week. He fulfilled his prediction by dying. Another case, somewhat similar, was told on Friday. A young man residing in the Ninth Ward has the measles, and caught it by imagination. His home is in the country, where he went a fortnight ago. A brother at that time told him how he had been exposed to measles over a month before and of his luck in escaping contagion, and when the young man, who boards in the city, returned he told his shopmates about his brother, adding that he felt sure he would take the disease. Every day he brooded over the matter, saying he knew he would get it, as it was just his luck, and sure enough he did get it, and is now ill at his boarding-house with the old-fashioned measles."

ERRATA.—In the letter on "Jenner and His Work" in THE LANCET of last week, the following corrections should be made in the extract from Sir John Simon's Vaccination Report, 1857:—page 1388, column 2, line 44, instead of "formally" read *formerly*; line 64, instead of "immortal" read *mortal*; line 72, the sentence should close with "fruitful" and a new sentence should begin with "To arm."—Mr. C. H. W. Remmett, the inventor and manufacturer of Lamp No. 4, referred to in our article on Safety Paraffin Lamps last week, writes to say that his present address is 37, Tarn-street, Newington-causeway.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Northampton Mercury, Wolverhampton Chronicle, Eastern Morning News, Leicester Post, Bury Guardian, Ayrshire Post, Times of India, North Star, Bradford Observer, Civilian, Pioneer Mail, Birmingham Post, Sheffield Weekly Independent, South Wales Daily News, Sussex Daily News, Jackson's Oxford Journal, Mid-Surrey Gazette, Scotsman, Architect, Birmingham Gazette, East Anglian Daily Times, Yorkshire Herald, Builder, Western Morning News, Goole Times, Hampshire Independent, Southampton Times, Liverpool Daily Post, Llandudno Directory, Brighton Argus, Derbyshire Advertiser, Yorkshire Post, Sanitary Record, Reading Mercury, Bristol Mercury, West Middlesex Standard, Leeds Mercury, Weekly Free Press and Aberdeen Herald, Local Government Chronicle, Mining Journal, Hertfordshire Mercury, City Press, Good Health, Family Doctor, Liverpool Review, Gloucestershire Chronicle, Macclesfield Courier and Herald, Surrey Advertiser, Local Government Journal, Chicago Dispatch, Dereham Standard, Lincolnshire Echo, Devon and Exeter Gazette, Freeman's Journal, Oban Times, Leyton Independent, West Middlesex Advertiser, Norwich Mercury, Carnarvon Herald, St. Andrews Citizen, Bedford Standard, &c., &c.*

The Erasmus Wilson Lectures

ON

THE GENERAL PATHOLOGY OF BONE,

Delivered before the Royal College of Surgeons of England on March 16th, 18th, and 20th, 1896,

BY W. G. SPENCER, F.R.C.S. ENG.,

SURGEON TO THE OUT-PATIENTS AND THROAT DEPARTMENT, WESTMINSTER HOSPITAL; LECTURER ON PHYSIOLOGY AT THE WESTMINSTER HOSPITAL MEDICAL SCHOOL, ETC.

LECTURE I.

Delivered on March 16th.

INTRODUCTION.

MR. PRESIDENT AND GENTLEMEN,—Much of that which concerns the bones is familiar to all, but interest is chiefly taken in them as passive agents; they are looked upon as rods jointed together, as levers upon which the muscles pull, or as bars broken or wrenched out of position by force or eaten away by disease. Now it is with the general diseases of bone, as distinct from the local, that I propose to deal in these lectures. I shall not give any systematic account of them, that would be largely a repetition of what can be found in text-books; but by discussing one after another some of the processes common to these general diseases I may hope to throw some light upon deviations from the normal functions of bone. When we consider the bones from this less common standpoint as organs taking part in the active changes of the body the general affections of the skeleton become still more interesting, for they are found no longer to be isolated phenomena, but to be really linked to one another by many common features. Little information about the normal function of bone can be gathered from direct observations of healthy bone or by experiments strictly physiological in character except on one or two points, such as the formation of blood corpuscles in the red marrow; for the rest, we have to depend upon the changes provoked by disease. The points which I shall take up are such as can be largely illustrated by pathological specimens in the museum of the College.

THE COMPARATIVE PHYSIOLOGY AND EMBRYOLOGY OF BONE.

When we regard bone as one of the tissues of the body which takes an active part in changes, whether physiological or pathological, it becomes desirable in the first place to form some idea as to the general relationship existing between bone and other structures.

A. The relation of the osteogenetic cells to the epidermis and to the central nervous system.—In low forms of life epidermal cells collect salts of lime from the surrounding medium and secrete them in combination with albuminous material in order to form a protecting covering. Certain epithelial cells in a mollusc secrete a simple shell, which serves not only as a protection but also as an attachment for muscles. A crustacean has a shell or exoskeleton formed by epidermal cells from which there are projections inwards. These act as an endoskeleton, offering favourable points for the attachment of muscles, the force and variety of whose contractions are thereby increased. In lower vertebrates bony plates, placoid scales or scutes may constitute an exoskeleton which co-exists with an endoskeleton of considerable complexity. There is an instance of this even among mammals in the armadillo and its extinct relatives. Furthermore, a study of the development of the endoskeleton in fish and amphibia shows that the cells which give rise to cartilage and bone originate in very close connexion with the epiderm. Bone is said to take its rise in mesoblast. But this term mesoblast does not denote cells sharply separated from the cells of the epiblast on the one hand, or from those of the hypoblast on the other. Indeed, one is tempted to use such words as "epimesoblast" and "hypomesoblast" in order to express the fact that certain mesoblastic tissues remain stamped with traces of their descent from one or other of the two layers of the bilaminar blastoderm. Even when some of the mesoblast has already been formed cells may continue to be budded off from the epiblast, and these, after sinking downwards into the mesoblast, become the originators of cartilage and bone. In those fish which have bone in the base of their scales cells of the epiderm produce both the scale and the bone. Cells budded off from the epiblastic layer of a salmon embryo have been traced to form the operculum, clavicle, and squamosal. The cartilage of the head of newts, such as Menobranchus or Necturus, has been also followed back to an origin from epidermal cells.[1] Although it may not be possible to demonstrate so clearly the same connexion for the chondroblasts and osteoblasts of higher vertebrates, yet it is evident that in them the skull, lower jaw, and spinal column are very closely connected with the epiblast during development, whilst it is known that the bones of the limbs spring from the same masses of cells as do the vertebræ. In the first place, therefore, the essential characteristic of the osteoblast—viz., the picking out salts of lime from the surrounding medium in order to secrete them in combination with albuminous material—is met with under its simplest form as a function of epiblastic cells. Secondly, cartilage and bone originate from cells which, although belonging to the layer of the mesoblast, arise close by or amongst the cells of the epiblast.

If a developmental relationship between the bones of the epiderm be allowed, some reason can be given for a pathological connexion between the bones on the one hand and the skin and central nervous system on the other. This developmental connexion is the more interesting because it can be made use of in order to throw some light upon abnormalities of the skeleton of which, as they happen before birth, the cause and the pathology are alike obscure. A sympathy on the part of the bones with the central nervous system brought about during the earliest periods of life by some common causes is illustrated in the following affections: anencephaly, acephaly, spina bifida, hydrocephalus, microcephalus and other kinds of congenital idiocy, congenital skin abnormalities, elephantiasis, or excess of skin with œdema, mikromelia, hydramnios (Salvetti) or adhesions of the amnion noted at birth,—all these occur along with irregularities in the development of the skeleton. The varieties of congenital bone disease have received a great number of names, for observers when examining specimens chiefly of premature or still-born fœtuses have been wont to liken the conditions they found to those diseases which affect the bones after birth. In this country the terms fœtal rickets, fœtal cretinism, fœtal scurvy, multiple fractures or fragility of bone in the fœtus are in common use. Foreign writers employ other names: chondritis fœtalis, mikromelica chondromalacia, vel pseudorachitica, osteogenesis imperfecta, rachitis annulans et mikromelica, achondroplasia, pseudochondritis, chondromalacia fœtalis, osteoporosis, dysplasie crétinoide, osteosclerosis and osteoporosis, aplasie périostale avec osteopsathyrosis (Kaufmann). We may remark of all these names that doubtless the one used by each writer most suitably described the general condition met with by him, nevertheless the general applicability of any of them when used as the name for a distinct disease of the fœtus may be as freely doubted.

Practically in all instances of congenital bone disease there is found a deficiency in length from impaired epiphyseal ossification. In some cases it is the preliminary formation of cartilage which is wanting; in the majority, however, the endochondral and periosteal formations are also deficient, so that the bones are friable; indeed, the diaphysis may be scarcely ossified at all. More rarely, along with marked deficiency in length, periosteal ossification has gone on to produce an eburnated, hard, and massive bone. But to compare the details of the changes occurring before birth with those due to disease in after life involves an obvious fallacy. No fœtal disease can be identified in its causation with rickets, scurvy, or cretinism, and to use such terms tends to beg the question of origin. The mothers have not suffered from rickets or scurvy. The so-called "fœtal cretinism" does not occur with any greater frequency in districts where goitre is endemic than in those places where goitre is only sporadic. Indeed, there is an essential obstacle to the inheritance of cretinism to be found in the fact that cretins are notoriously sterile. Children of goitrous

[1] Platt: Klaatsch.

Digitized by Google

parents living in an infected region are born quite healthy, and only show signs of cretinism after some months. All evidence tends to limit the cause of cretinism to the water drunk (Kocher). The removal, however, of the thyroid gland from a pregnant bitch is said to cause the puppies to be born with "rickets." In some diseased fœtuses the thyroid gland has been affected or has been noted to be absent, but in others with apparently similar bone lesions the thyroid gland was normal (Shattock). Therefore, neither disease nor absence of the thyroid gland can be a general cause of fœtal bone affections. After birth, however, the thyroid gland becomes such an important factor that both removal and disease, in proportion to its severity, check growth of the bones in length. An absolute arrest of growth took place in a boy aged ten after thyroidectomy, so that he was found eighteen years afterwards to be no taller than at the operation. The removal of the thyroid gland from young rabbits and lambs likewise arrests growth. The epiphyseal ossification ceases, the cartilage cells stop proliferating and become either flattened or distended with fluid. Fibrous tissue grows in from the periosteum and so separates the epiphysis functionally from the diaphysis. It is well known that as a consequence of removal or disease of the thyroid gland affections of the central nervous system and of the skin occur, forming another illustration of the sympathy which connects the bones with the skin and central nervous system.

When in the decline of life the central nervous system suffers excessive fragility of bone may be found, especially in insane and ataxic patients. Gigantic overgrowth, whether of the skeleton as a whole or of part or of the extremities, may be accompanied by similar overgrowths of the skin. In the case of the so-called "elephant man" described by Treves there was a hypertrophy of half the skull and of the right upper limb and feet co-existing with an enormous hypertrophy of the skin. It will be noted that in the comparatively simple cases where one or more of the toes or fingers are affected the overgrowth of the bone is *pari passu* with the skin. Further on I shall refer to two other points in which bone resembles skin, to the possibility of transplanting bone, and the tendency of periosteal sarcomata to spread rapidly by way of the lymphatics and lymphatic glands like the carcinomata.

B. The relations of the bone marrow to the vascular system and to the lymphadenoid tissues.—The bone marrow cells have functions totally different from the osteogenetic cells; in one respect, indeed, the action of the latter is the reverse of the former, for they absorb bone instead of forming it. Bone is absorbed by a process of digestion on the part of the marrow cells; not only does this process affect the septa surrounding the marrow cavity, but also any foreign bone inserted into the medullary cavity is likewise removed. The lymphadenoid tissues—the spleen, lymphatic glands, and thymus as well as the bone marrow—all originate in close connexion with the bloodvessels from the splanchnopleural layer of the mesoblast which surrounds the hypoblast of the alimentary canal. First of all, some of the cells of the splanchnopleure form the walls of the vessels whilst others produce the blood corpuscles. At a later stage lymphadenoid tissue arises in the connective tissue around blood capillaries by the white cells which have emigrated collecting in the fine meshwork (Gulland). The bone marrow forms from the vessels which push their way into the previously solid cartilages. These structures—the spleen, the lymphatic glands, and bone marrow—produce red as well as white corpuscles during fœtal life. In the adult the production of red corpuscles is no doubt confined on the whole to the red bone marrow, but whenever a more rapid formation is required—e.g., in order to make good losses by acute hæmorrhage—the spleen supplements the red marrow. The absorptive or digestive properties of certain marrow cells is a feature shared in common with the cells of lymphadenoid tissue. It is especially well marked in the lymphatic gland tissues surrounding the alimentary canal. I may recall the fact that Metchnikoff took one of his earliest instances of the digestive properties of these cells from those which are found around the alimentary canal of the water flea, Daphnia, whilst later Ruffer described the phagocytic properties of the cells in Peyer's patches. It is well known that the general diseases of the bone marrow are closely allied to those of the spleen and to those of the lymphatic glands, the chief features of which are anæmia or leucocythæmia, with new growths such as myeloma and lymphadenoma (Spencer).

THE EFFECT OF ALTERATIONS IN THE CIRCULATION OF THE BLOOD THROUGH BONE.

In many books one may find bone formation and bone absorption, hypertrophy and atrophy, hyperplastic and atrophic inflammations ascribed both to an increase and also to a decrease in the amount of blood circulating through the bone. In such different conditions as mollities ossium and osteitis deformans the same observations may be met with—viz., that the bones were "excessively vascular," "congested," "contained much blood," &c. Something is evidently wanting to the explanation when one and the same result, atrophy, is attributed both to an increased vascularity and to a diminished vascularity, when an increased vascularity can be said to promote both bone formation as well as bone absorption. In vascularity as found post mortem there is no distinction between the arterial and venous forms. Observations have to be made at surgical operations on this point.

A. A slight increase in the arterial blood-supply favours bone formation and normally occurs in those parts of bone in which growth is active—A relatively large supply of blood to any tissue corresponds with physiological activity, and conversely physiological activity necessitates a correspondingly large blood-supply. During the years of growth, especially between ten and seventeen, the greatest activity is at the epiphyseal and diaphyseal junction. The epiphyseal end of the bone, at which growth is most rapid, has the greater blood-supply. The lower epiphysis of the femur, the upper epiphysis of the tibia, the upper epiphysis of the humerus, and the lower epiphysis of the radius are sites of active growth. The course of the nutrient artery in these bones may be held to favour the blood-supply to the epiphyses above mentioned. Any injury which tends to separate an epiphysis from its diaphysis during the growing period is always attended by the extravasation of much blood on account of the previously existing vascularity. During the active period of growth the vascularity may be so increased as to be a cause of actual pain—"growing pains" (Poncet). There can be no doubt, moreover, that it is this special vascularity of growing bone which causes the juxta-epiphysary ends to become so frequently the seat of septic inflammations. The greater the vascularity the more easily will extravasation and thrombosis follow upon a slight injury. The greater the vascularity the more likely are the micro-organisms which chance to be in the blood to reach to and to settle down in the blood-clot. The frequency with which boys between thirteen and seventeen are attacked by acute inflammations in the lower end of the femur or in the upper end of the tibia may be compared with the relative freedom from attack on the part of girls of the same age. The tendency to anæmia in consequence of menstruation along with the smaller bone formation and muscular activity in girls supplies a ready explanation of the smaller vascular supply and thus the rarer occurrence of septic inflammations. A slight increase of the arterial supply to an epiphysis such as results from disease in the middle of the shaft of the bone may cause a disproportionate growth of the bone in length. Very rapid growth of the bones in length may follow the occurrence of a continuous fever—e.g., typhoid fever—apparently from the greater blood-supply to the bones during the course of the fever. An active use of muscles not only improves their own blood-supply, but also that of the bone to which they are attached. Thus by muscular exercise the development of the skeleton as a whole is favoured. But also, as will afterwards be mentioned, the part of any bone of an adult to which active muscles are attached has a larger blood-supply than the rest.

B. Any considerable increase of the arterial blood-supply to bone promotes its absorption—1. The absorption of the preliminary cartilage during the development of bone is brought about by the entrance of bloodvessels from the periosteum, which thus are said to vascularise the calcified cartilage. 2. An absorption of the pre-existing tissue by means of cells having digestive or phagocytic properties takes place in consequence of the increased arterial blood-supply which constitutes an acute inflammation whether of bone or of the soft parts. In the course of operations for acute epiphysitis surgeons have frequent opportunities of observing how much absorption of bone has happened during the few days that the inflammation has lasted. 3. If a foot be wrenched and so an increased arterial blood-supply or inflammation be brought about in the ligaments, these ligaments will then yield to a force which they would have completely resisted before the inflammation had promoted absorption. So, also,

Digitized by Google

if in order to correct the rickety curve of a long bone a strain short of breaking be put upon the bone traumatic inflammation and absorption are caused, so that a week afterwards it will bend or break when the same amount of force is again applied. A slight injury to the limb of a growing boy has been sufficient to cause bending or fracture some time afterwards on account of the absorption which had in the meanwhile gone on. 4. The absorption of bone from increased vascularity is not necessarily connected with inflammation. Nævi or the larger angiomata, the true aneurysms of bone, may produce such an increase of the arterial circulation as to stimulate the absorptive properties of the osteoclasts.

When an attack of scurvy causes an increased arterial blood-supply to the periosteum and bone absorption is very rapid the compact bone becomes very porous or cancellous, the medullary cavity enlarges, and spontaneous fractures occur. When young children are attacked extravasations of blood take place in the neighbourhood of the epiphyses. In adults there may be so much tendency to absorption as to prevent the formation of any callus should a fracture occur during the attack of scurvy. If the scurvy follow shortly after a fracture there may be rapid absorption of callus already formed, so that the fragments again move on one another. Likewise the teeth in such cases become loose and fall out, owing to the absorption going on in the alveoli. Hæmophilia also induces excessive absorption of bone.

C. A diminution in the arterial blood-supply checks the formation of bone whilst absorption continues, so that "eccentric atrophy" is brought about.—As a result of the diminution in the arterial blood-supply the compact bone tends to become cancellous, and the cancellous bone is in its turn absorbed so that the whole shaft may be reduced to a mere shell. There is no evidence of any greater rapidity of absorption than normal. It is the want of a steady formation of bone which is the chief factor. As a consequence of disuse, whether due to ankylosis of a joint or to paralysis, the blood-supply diminishes both to the muscles and to the bones, and hence there follows a marked atrophy of bone. "Eccentric atrophy" regularly occurs as a senile change, varying very much in degree in different cases, and the gradual decline in the periosteal bone formation is the more marked the greater the disuse of the muscles.

Mollities ossium or osteomalacia.—Mollities ossium has been so often used as the name for a variety of affections in which a common end—viz., softening, bending, and pathological fractures—has been attained in such different ways that neither it nor its synonym, osteomalacia, can be applied as the term for a special disease. It is necessary to distinguish—(*a*) fœtal osteomalacia, which has been referred to; (*b*) infantile osteomalacia due to scurvy, which has also been referred to; (*c*) rickety osteomalacia arising in childhood and youth from errors in diet or hygiene (vide *infra*); and (*d*) fragility of bone or osteopsathyrosis.

Some typical cases of fragilitas ossium may be classed as spontaneous pathological variations, a condition which may appear in several members of the same family, for like other spontaneous variations the fragility may be transmitted to some of the descendants, tending soon, however, to die out. Still one can scarcely ever exclude the possibility that other tendencies to fragility have been present. The occurrence in several members of the same family may be due to a similarity of environment, exposing them to the action of causes allied to those producing rickets. The disuse and often distortion of the limb following on the multiple fractures, by lessening the patient's muscular activity, may reduce the circulation below the normal and so lead to "eccentric atrophy." Moreover fragility is the more frequent among girls about puberty (vide *infra*).

Mollities ossium of pregnancy occurs with such frequency in certain places—notably in some of the lateral valleys of the Rhine—as to be there termed endemic. Such facts must be considered by the side of observations made on animals. Certain pastures may give rise to osteomalacia owing to unfavourable seasons, excesses of cold and damp, or, on the other hand, in times of drought. So many cases have before now happened in the same district as to cause the disease to be then regarded as an epizootic one. From this point of view the osteomalacia of pregnancy is allied in its causation to rickets, the general nutrition being impaired, whether by bad food or unfavourable surroundings or by both. But the mollities ossium of pregnancy is connected in some way with the activity of the ovaries, even when the disease has occurred in regions where its frequency has given rise to the notion of a supposed endemic origin. It has been long known that a case of osteomalacia until then progressing may become arrested at the climacteric and the bones even harden again. Of recent years the climacteric has been artificially induced by removing the ovaries, and this so often that the success of the operation is beyond question (Fehling and others). Patients long bed-ridden may soon be able after double oöphorectomy to get up and walk, the bones being again enabled to bear the weight of the body. Some important light has been thrown upon the mollities by the examination of the bones of women dying in the course of normal pregnancy. An increased vascularity has been noted especially in the pelvis and femora, with signs of increased absorption of bone, so that many septa were found covered by a layer of decalcified fibrous tissue (osteoid tissue). That the pelvis and femora are very vascular, due to an increased arterial blood-supply, in mollities ossium of pregnancy I observed myself in a goat which I examined shortly after it had given birth to a kid. The animal was suffering from marked softening and bending of the pelvis and spontaneous fracture of both femora had occurred. I may here observe that such specimens kept in spirit do not preserve the condition existing during life, glycerine must be employed instead. In confirmation of the increased arterial supply to the pelvis and femora I may refer to the fact that the first signs of mollities ossium in pregnancy are aching pains in these bones, and even during normal pregnancies slight but similar pains in the same bones may be met with. Moreover, in confirmation of the excessive absorption due to the increased arterial supply we have the same noted as in the scurvy of adults concerning the delay or non-union of fractures at that in an otherwise perfectly healthy woman. Definite callus may not form until the termination of pregnancy. Excision of the knee-joint in a pregnant woman, the cut surfaces being left healthy, was followed by non-union and dislocation backwards, requiring subsequent amputation. Women who suffer from osteomalacia have been abnormally fertile. It seems, therefore, that the slightly increased vascularity in the pelvis and femora attending a normal pregnancy may become in an excessively fertile woman further increased, and produces the excessive absorption in the pelvis and femora. Girls about puberty suffer from forms of osteomalacia, indicating a connexion with the activity of the ovaries but not necessarily with pregnancy. Sometimes the facts are stated in this way—viz., that the fragilitas ossium occurs most frequently in girls. If osteomalacia occur in a girl about puberty its course may be arrested and restoration of the bones brought about by oöphorectomy. Von Recklinghausen considers the increased arterial blood-supply amounts practically to an inflammation, so that osteomalacia from this point of view may be called osteitis fibrosa. Osteomalacia is not entirely and exclusively an absorption of bone, for irregular formations of bone, osteophytes, &c, have been found.

With *senile osteomalacia* must be classed the osteomalacia of lunatics, of ataxia, and other nervous diseases, as well as that occurring in wasting disease, excluding new growth. In all these cases the "eccentric atrophy,"—i.e, a diminished periosteal formation with absorption continuing, is at bottom due to impaired general nutrition in addition to disturbance of nerve influence.

NORTH-EASTERN CHILDREN'S HOSPITAL.—The twenty-eighth annual meeting of the governors of this hospital was held on May 13th at Devonshire House, Bishopsgate-street, under the presidency of Mr. J. Lister-Godlee. The deficiency shown on the balance-sheet had been reduced during the year from £5323 to £2820, and the mortgage debt had been reduced from £4500 to £3000. With the object of helping further to get rid of the debt still existing there is to be a grand rose *fête* and bazaar at the Queen's Hall on June 23rd, 24th, and 25th, which will be opened on the first day by the Duchess of Connaught.

LITERARY INTELLIGENCE.—The publication (S. Hirsch, Leipzig) is announced of a "Text-book of Gynæcological Diagnosis" ("Lehrbuch der Gynecologischen Diagnostik") by Professor G. Winter and Carl Ruge of Berlin. It contains twenty plates and 140 engravings (partly coloured) in the text. From the specimen pages and illustrations contained in the prospectus announcing the work it would appear to be clear, concise, and practical. The publication price is 14 marks (14*s*.)

RATIONAL THERAPEUTICS AND THE USE OF COMMON REMEDIES.[1]

BY SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN AND DEMONSTRATOR OF PRACTICAL MEDICINE AT ST. BARTHOLOMEW'S HOSPITAL, SENIOR PHYSICIAN TO THE ROYAL FREE HOSPITAL, ETC.

THERE is, I think, no better work that we can do as practitioners of medicine than to meet together from time to time in a friendly and informal manner in order to discuss the drugs we are prescribing every day and to compare notes of our experience as to their use. Therapeutics has not yet passed out of the empirical stage, and from whatever source the suggested remedy comes its value has to be tested and proved at the bedside. It is to empiricism tested by bedside observation that medicine owes most of the remedies it finds of use. Yet we often hear this empirical bedside study of the action of remedies spoken of with disparagement, as if it were the opposite of rational, and it was a protest against this misuse of terms that formed one of the most striking passages in Dr. Gowers' recent address. Essentially false as the opposition between empirical and rational really is, it is based upon a laudable desire to bring therapeutics into closer relation with the general principles of science. Unfortunately, this is but a pious wish and not yet an achieved fact. The same confusion between a wish and a fact finds expression in another form in the contrast that is often made between pharmacology and therapeutics.

Pharmacology is a word of recent introduction. Ending in "logy" it is assumed to be a science, and, being a new word, to denote a new science. Now, it will be well to see how far this claim is just. I take down from my shelf some recent book which bears upon its back the title "Pharmacology," and another, written but twenty years ago, labeled "Therapeutics." I turn up in both the same drugs, and what do I find? First, an account of the crude substance and of the sources whence it is derived; then an account of its chemical constitution, of the methods by which the substance can be obtained, the impurities which are present, and the way in which they may be detected and removed; next the results of the physiological investigations into the action of the drug, for the most part performed in the physiological laboratory, upon lower animals, with a summary of the conclusions to be drawn from these experiments and the suggested application to their use in disease; and in all these respects there is no greater difference between the two accounts than the lapse of time and the progress of knowledge accounts for. But the greater part of the account in each case alike is formed, as would be expected, of a statement of the effect of the drugs upon man in health and in various conditions of disease. This part forms three-quarters, nine-tenths, or in some cases even more, of the whole. And how has it been obtained? By clinical observations such as you and I can make and are making every day. If, then, we take away from the account given of any remedy the materia-medical, therapeutic, and toxicological parts, there is nothing left for pharmacology but the physiological action of the drug upon animals, in which special subject of recent years great advance has been made. In this sense pharmacology as distinguished from what used to be called therapeutics comes to be nothing more than a special department of Applied Physiology.

The term is, however, often used in a less restricted sense, and taken in a general way to mean all methods of treatment and the explanations to be given of their mode of action. Thus of quite recent modern books on this subject some, like Ringer's in this country and Wood's in America, are entitled "Therapeutics"; others, like Brunton's, "Materia Medica, Pharmacology, and Therapeutics"; while others, especially on the Continent, bear the simple title of "Pharmacology." Yet there is no difference in the contents of any of these books, the difference lies all in the title—Pharmacology; this proves to be, in fact, but a new name for the old Therapeutics—Rationalistic Therapeutics, if we like to call it so—in which all the sciences, chemistry, physics, physiology, and pathology, are called into requisition to give or to suggest explanations of the results at which clinical observation has arrived. This double use of the term is responsible for much confusion and misconception. The most serious differences between men arise, not so much about things or facts, but because of words the meanings of which have not been accurately defined; and so it is with pharmacology. At the present time this matter has a practical bearing, for everywhere examinations for medical students are being instituted in this subject, and it becomes therefore necessary to define exactly what is meant. We should all agree that we ought to send our students out into practice as highly equipped as possible with therapeutic knowledge and to train them so that they should be able, not only to practise therapeutics, but to think and reason about the ways in which their remedies act, and this knowledge must be tested by examination; but it does not follow that an examination in a special department of applied physiology is also necessary for the purpose. Indeed, the requiring of such examinations seems to rest upon the assumption that therapeutics is an art based upon a science of pharmacology—in other words, that therapeutics is applied pharmacology. Put in this form the fallacy is obvious. It is an absolute reversal of the real relation between the two subjects at the present time, for even the most recent works on pharmacology contain, as stated, comparatively little beyond that which has been derived from empirical therapeutics. We trust this will not always be so, but it cannot be denied that this is the case at the present time.

This subject has a special bearing upon the present discussion, for none of us, I presume, claim to be pharmacologists in the limited sense of pharmacological physiologists, yet we are all therapeutists, and, I believe, thoughtful therapeutists. We use the remedies which experience recommends, and must therefore, I suppose, be considered empirics. Yet we bring to bear all our powers of clinical observation to determine the conditions under which these remedies act, and we try to find if we can some scientific reason why they produce their result. If we can get good reasons we are glad; if not we continue at any rate to use the remedies which we know by observation prove beneficial. If this is not rational treatment, what is it? We may at any rate claim to be rationalistic therapeutists. The real difference between a pharmacological physiologist and a clinical therapeutist is but one of method and of place. Each has an equal desire to know how remedies act and each attempts to solve the problem in his own way. The objects are the same, the methods different. Each field of research is necessary to the other, and each real worker knows it. The special line of research is determined by the man's opportunity and his taste. The physiologist investigates his remedy in the physiological laboratory upon animals, and he has the great advantage that he can modify his experiments at will and make them at his own time and in his own way. The clinical therapeutist's laboratory is the sick room or hospital ward; the subject of his experiments is man, not healthy man, but sick; the conditions of experiments he cannot vary for himself at will; he must take the patient as he is presented to him, at a time which he cannot choose, and when he is perhaps least inclined or fitted for such investigation. But the greater the difficulty the greater the honour of achievement, and I think no one will deny that the difficulties of the clinical investigation of the action of drugs are out of all proportion greater than those which attend physiological investigation. It is perhaps in their suggestiveness that the physiological and chemical studies of remedies have their chief value. For instance, how suggestive is the theory that substances with like chemical constitution have similar physiological action, and what a field of research does it seem to open out. To what brilliant results are Pasteur's observations on fermentation and the lower organisms already leading. Yet is not bedside observation rich in suggestions too? Can we afford to discourage, slight, or despise them because they come from another source than pure science, those happy thoughts, ideas, inspirations we might almost call them, seeds which chance and casual observation dropped into an observant mind? Is not Jenner's discovery of vaccination receiving at last the scientific explanation in Pasteur's work, and shall we call Pasteur's work rational and deny the term to Jenner's?

Yet, after all, wherever the idea comes from, whether from the chemist, physiologist, pathologist, or busy practitioner, in all cases alike, it is at the bedside that it must be tested. This is, after all, the crucial test, whatever the theory

[1] An introduction to a discussion, read before the Willesden and District Medical Society on Jan. 17th, 1896.

Digitized by Google

be. Many remedies we use and cannot tell why they do good, though we much wish to know; experience proves their value, therefore they must be used. On the other hand, many remedies which come to us rich in scientific promise put to the test prove not to fulfil the promises they held out. Surely it would be as irrational to discard the first as to continue to use the latter.

Rational therapeutics consist in the use of remedies which we know to do good, whether we seem to understand their mode of action or not. But before we endeavour to explain a result we must know whether it is a fact or not, otherwise we are but beating the air. This constant testing and proving of stated facts is the chief function of the therapeutist and for the carrying on of certain lines of such research those have great advantages who are attending patients in their own homes. On practical points of this kind it is that discussions such as that which I have the honour to introduce are likely to prove full of instruction and profit.

The drugs which have been selected for consideration are five: iodide of potassium, liquor arsenicalis, tincture of digitalis, liquor strychniæ, and antipyrin. I propose to take them one by one, for in this way I think the discussion will be more precise and profitable.

IODIDE OF POTASSIUM.

The first on the list is iodide of potassium and this drug illustrates very well the evolution of the science of therapeutics. Crushed sponge was known as a successful remedy for goitre in the thirteenth century and it is probable that it was used by the Chinese much earlier. Fucus vesiculosus was also used later for the same purpose. Iodine was discovered by Courtois in 1811. In 1820 Coimdet of Geneva, finding that both these remedies contained iodine, suspected that iodine was the active agent in the cure, and his theory when put to the test proved to be correct. He extended its use to the treatment of scrofulous glands, and then came the discovery of its action in syphilis in 1831 and of its effect in the elimination of lead and mercury from the body in 1844. Further investigation has shown that iodide of potassium is eliminated chiefly by the kidneys, but it is found in the blood, saliva, milk, and even in the urine of a sucking child of a mother who is taking the drug, and that it is present also in the skin, liver, spleen, lymph glands, and muscle, but not in the brain. Its physiological action is not understood, and nearly all our knowledge of the drug is derived from the result of clinical observation—i.e., it is simply empirical therapeutics.

Syphilis.—On the use of iodide of potassium in syphilis there is no need to dilate. The rapidity with which tertiary lesions, such as periosteal nodes, skin eruptions, and iritis, disappear under its action are among the triumphs of therapeutics. Take again a patient with third nerve paralysis. What a comfort it is to know that as such a lesion is almost always syphilitic it will get well under iodide of potassium. In the early stages of syphilis the diagnosis is usually easy, but it is in the later stages that difficulties of diagnosis begin. It is then that diseases of the nervous system and of the viscera prevail. It is then that nondescript nervous symptoms develop: pains in the joints, pains in the bones and head, over the liver and in the abdomen, and even in the chest; perhaps paroxysms of intense neuralgia. Treatment on general lines has been tried without success until the syphilitic origin is at last suspected, and iodide of potassium effects the cure. Perhaps some of the most striking cases are those in which profound cachexia develops without obvious cause, a condition common enough in children and generally recognised, but not rare either in the adult. I saw a young woman some time ago who was healthy until marriage, and although she had had no sign of syphilis, and her medical attendant could not believe that she had been syphilised, yet her husband was known to have led a loose life, and iodide of potassium restored her to health when iron and all other treatment had failed. I saw a man not long ago with symptoms which might have been due to advanced multiple sclerosis or even, except for the want of mental symptoms, general paralysis of the insane, in whom no history of syphilis could be obtained, yet iodide of potassium and rest rapidly cured him, and the case was doubtless of a syphilitic nature. Of the cure of syphilitic diseases of the nervous system by iodide of potassium we must speak with caution, yet all will admit the benefit the drug does, though the question of complete cure may be more difficult to answer. I do not think we can go so far as to say that the cure of a doubtful disease by iodide of potassium is certain proof of specific origin, but in many cases it certainly is strong presumptive evidence. No doubt much depends upon the stage of the disease. The most advanced forms of syphilis of the nervous system consist in fibroid degenerations, and we can no more expect to remove these by drugs than we can to charm away the scar of the syphilitic ulcer in the skin. Yet in the early stages of syphilitic infiltration we may expect to do, and really probably succeed in doing, as much as we see daily happen under the action of the drug in the skin and superficial parts of the body. It is in the early stages of syphilitic disease of the nervous system, when the lesions are recent and gummatous, that cure may be effected, not in the later, when irreparable damage has been done and the wasted nervous structures have been replaced by fibrous tissue. It is in these stages, when the nervous affection can hardly be definitely named and before it can be called, e.g., tabes dorsalis or lateral sclerosis, that the good may be done and, as in some of the cases mentioned, apparent cure be the result of treatment. It is usually stated that in cases of syphilis which have been already treated with mercury iodide of potassium converts the insoluble compound which is supposed to be formed between mercury and the tissues into a soluble one, thus setting the mercury free again, and it is in this way that the salivation sometimes caused by iodide of potassium in these cases is explained. It is, however, proved that iodide of potassium has a curative effect on syphilis in a person who has taken no mercury at all. It would be interesting to hear of instances of this kind, for in the present day, when syphilis is treated with mercury as a matter of routine, such cases are necessarily rare.

Poisoning with lead and mercury.—There can be no doubt of the effect which iodide of potassium has in promoting the elimination of these two metals in cases in which symptoms have been produced by them. Clinical experience is confirmed by the chemical examination of the urine in which the administration of the drug is increased by an increased elimination of the metal. These metals form insoluble compounds with albumin and thus become fixed in the tissues. Iodine releases them and does so, it is supposed, by forming a soluble substance by double combination with the metal and albumin. This pharmacological explanation even if it proved to be incorrect would not affect the correctness of the clinical observations.

Aneurysm.—A great deal has been written about the efficacy of iodide of potassium in aneurysms, especially intra-thoracic aneurysms of large size, and I think there can be no doubt that it does relieve the pain and lead to diminution in the size of the sac, yet it is not easy to determine this point because the patient is usually at the same time being treated in other ways—e.g., by diet and complete rest. Certainly the improvement is not due simply to coagulation in the sac, for in many cases where much relief has been experienced the sac has been found empty of clot. It is tempting to believe, inasmuch as so many aneurysms are the result of syphilitic disease of the arteries, that iodide of potassium might cure them; but whatever action it might have upon early syphilitic disease of the vessels (and of this there can be little doubt) it can hardly be expected to produce any effect when a large aneurysm has formed, for the aneurysm is the consequence of past syphilitic disease and not associated in all probability with any active disease of the kind. The accepted explanation is that the iodide of potassium reduces blood pressure and diminishes the force of the heart's contraction, the aneurysmal sac being thus permitted to contract and the symptoms being relieved.

Rheumatism.—Iodide of potassium is one of the stock remedies for all forms of muscular rheumatism, though its place is being taken to a great extent now by salicylate of soda. In the same way it is one of the stock remedies for all forms of the chronic joint troubles which are called by the generic term of "rheumatism." It is, however, entirely without effect in rheumatic fever, a specific affection which, in my opinion, has nothing whatever to do with the great majority of cases which we call rheumatism in this country. Its effect is most striking perhaps in those cases of chronic rheumatism or gout which are associated with chronic lead poisoning.

Diseases of the chest.—In the treatment of diseases of the chest iodide of potassium does not play any great part. It seems to be of service in some cases of chronic bronchitis, possibly because it is excreted by the mucous membrane of the bronchi, as it is by all other mucous membranes. In

Digitized by Google

asthma it certainly is a remedy of use, not so much at the time of the paroxysms as between the attacks, and it appears to have the effect of diminishing their frequency. Certainly, many asthmatic patients believe in the drug and attribute a great benefit to the taking of it. In plastic bronchitis it is said to be the only remedy which is of any service at all, and so far as my experience goes, which now extends to several cases, I certainly endorse that opinion.

Iodide of potassium appears to be an alterative—i.e., to have a subtle influence upon cell nutrition. For this reason it is largely given in the chronic processes of inflammation, with a view of controlling it or of removing its products. It is thus one of the chief routine remedies for almost all chronic inflammatory affections of the joints, especially of the serous membrane—e.g., of the joints and pleura. As an alterative also it is given in all forms of enlargement of the lymphatic glands, especially those of a tuberculous nature, and it is stated to have a strong action upon certain other glands, especially the testicle and the mamma; thus it is an efficient galactogogue, while prolonged administration of the drug may, it is stated, lead to atrophy of the testicles. It will be interesting to have any confirmation of these statements, of which I have no personal experience to bring forward. Upon dropsy it has been said to have a specific effect, but there are so many causes of dropsy, and the term is such a loose, indefinite one, that it is hard to know exactly what is meant. In diseases of the skin it is not much employed, unless in those of a syphilitic nature; but I have seen it do much good in large doses in scleroderma.

I now come to a very interesting part of my subject—viz., the consideration of the peculiar effects which are sometimes produced by the administration of the drug; and here we are brought face to face at once with one of the most disturbing factors in therapeutics—viz., idiosyncrasy, that great stumbling block in the way of applying any physiological results upon animals to man or even without caution to all men alike. Iodism in its ordinary form of headache and catarrh I need hardly do more than mention. I suppose we may assert that it is capable of being produced in every patient, yet there are striking differences in this respect following in one case the administration of the smallest dose, while in others not appearing until very considerable doses have been taken for some time. As iodism is one of the practical difficulties we have to deal with in the administration of the drug it will be well, therefore, to consider what means there are of obviating it. It is in many patients a merely transitory phenomenon, and after two or three days the symptoms pass off, though the dose has not been changed, and even if the dose has been increased; indeed, it has been paradoxically asserted that the cure for iodism is to double the dose. The subsidence of symptoms is aided often by the administration of a saline purge. Usually if the medicine be reduced or stopped for a day or two until the symptoms have passed off its administration may be then resumed and iodism will not return; but in some cases the idiosyncrasy is so marked that even the smallest dose produces the effect, and nothing short of the entire giving up of the drug will suffice. But before this it will be well to try whether the iodide of ammonium or of soda is not tolerated better. It is stated that the addition of carbonate of ammonia or of the aromatic spirit of ammonia to the mixture will check the occurrence of iodism, but I have failed to satisfy myself of this, and so I see has Ringer. Another form of iodism, though not quite so common as the catarrhal form, is that in which the drug causes great depression of mind and body, often without coryza or any other of the common symptoms. Sometimes it upsets the digestive organs, causing loss of appetite, nausea, vomiting, or watery purging. Puffiness and swelling beneath the eyes are not uncommon with marked coryza, but they occasionally occur without it, thus giving the face a renal aspect. Salivation and diaphoresis are also stated to be occasional results, but I cannot say that I have observed them.

The iodide eruptions have always excited interest. The commonest of them is acne, and this occurs in the usual places, but the acne spots are often of considerable size and attended with a good deal of inflammatory induration. Upon the face, usually associated with acne, a butterfly eruption is often seen, of an eczematous type, extending beneath the eyelids and across the bridge of the nose, and in most of these cases there are well-marked acne spots on the lower part of the nose and cheek. The most striking iodide eruptions, and those most commonly meant by the name, are those which are pustular or even bullous in character, and their usual seat is the face; and, strange to say, some of the most marked forms of eruption have appeared some time after the administration of the drug has been suspended. General diffuse erythema is met with sometimes over the whole body, but it is stated to be rare. I do not think it is so uncommon on the legs, and in this position it is often hæmorrhagic. A patient came under my treatment for a punctate hæmorrhagic erythema of the leg and he volunteered the statement that, among the many things that would produce it, iodide of potassium was the principal. I was subsequently enabled to observe that the administration of a few grains of iodide of potassium brought out markedly hæmorrhagic erythema. Lastly, cases of general purpura have been described, and one or two of these have proved fatal, but this condition is extremely rare.

The effect of iodine upon the lesions of syphilis has led to its use in other specific affections, especially, for instance, tubercle. In tuberculous affections of the lymphatic glands, as well as in tuberculous affections of the peritoneum and perhaps of the pleura, it does seem to have some effect. In phthisis and in tuberculous peritonitis I believe it to be useful. There is one other rare but remarkable disease in which it seems to be by far the most effectual remedy we possess: I refer to actinomycosis. In a little patient recently under my care suffering from this disease involving the pleura and chest-walls, the child, who had been reduced to a shadow and looked desperately ill, made no improvement until iodide of potassium was administered, and then at once gained flesh, colour, and strength, and seemed as if he might recover. Unfortunately, he died by misadventure during the administration of chloroform given for the purpose of opening one of the small abscesses.

The therapeutics of iodide of potassium open out a very large field of discussion, but there are, I think, one or two points upon which information would be specially valuable—viz., (1) iodism and the means of counteracting it; (2) iodide rashes and the way to remove them; (3) examples of peculiar idiosyncrasies; (4) instances in which the drug has caused stoppage of the secretion of milk or atrophy of the testicles, free purgation, or vomiting; and (5) instances in which effects have been produced upon a suckling child through the milk of the mother while taking the drug.

In respect of the mode of administration it is usually given in solution in water or it may be given in milk. One point has come out in recent years—viz., that very large doses of the drug may succeed in producing an effect when small ones have failed, and the amount so given in the twenty-four hours sometimes reaches extraordinary dimensions, even to the extent of four or five ounces.

LIQUOR ARSENICALIS.

The next remedy on the list is liquor arsenicalis. The history of arsenic in therapeutics is interesting from our present point of view. It was known to the ancients in the form of orpiment and sandarach or realgar. Dioscorides gives the following description of the drug: "Orpiment, auri-pigmentum—i.e., the yellow sulphide—is astringent and corrosive, burning the skin with severe pain with the production of an eschar. It removes fungous flesh and is a depilatory." He then describes sandarach or realgar—the red sulphide—in the same terms, stating that, "mixed with resin, it causes hair to grow when destroyed by pellagra, and that with pitch it removes rough and deformed nails. With oil it is used to destroy lice, to dissolve abscesses, to heal ulcers of the nose (probably lupus), of the mouth, and fundament (probably epithelioma). With wine it is given for fetid expectoration, and its vapours, with those of resin, are inhaled in chronic cough. With honey it clears the voice and with resin is very excellent for shortness of breath." In China it was used from very early times as an application to venomous wounds, also as a remedy for ague and as a tonic in several diseases. For skin diseases it has been employed by the Hindoos for centuries, though its use was not introduced for this purpose into this country until the end of last and the beginning of this century. It was introduced into Europe about the beginning of the seventeenth century, and was then used as a remedy for pulmonary affections associated with dyspnœa, probably asthma and chronic bronchitis, as well as for different forms of ague. The analysis of a patent ague medicine by Fowler, and the discovery in it of arsenic, led to its extensive use for intermittent fever in this country; and at the end of last century it was a common remedy also for various scaly skin eruptions and for neuralgia. After having had a period

Digitized by Google

of popularity it fell into disuse and was almost forgotten until Boudin, in the middle of this century, resuscitated it, and since that time it has been one of our stock remedies for all the affections named. Of recent years numerous experiments have been performed on animals, and they seem to show that arsenic has a definite effect upon the nervous system, especially upon the cardiac ganglia and respiratory centres; but it is difficult to see any relation between the results of these experiments and the action of the drug in man; so that we are indebted again for our knowledge of the action of this drug in disease simply to observation upon man—in fact, to the oft-disparaged empiricism, or, as I should prefer to call it, to thoughtful clinical observation. I do not propose to speak of the local action of arsenic externally, but only of its internal use as a physic; and this limitation, I believe, the committee desired, when they placed upon the list they first sent me, not "arsenic," but "liquor arsenicalis."

The facts about the drug other than clinical which have been discovered by clinical and pathological investigation are these: that arsenic is rapidly absorbed from the stomach and found in a few minutes in the circulation; that it is eliminated chiefly by the urine and sweat, and also by the mucous membrane and glands; but the elimination takes place slowly, so that arsenic may be detected a fortnight or more after it has been stopped. It is also eliminated by the liver, and in full doses causes fatty degeneration of both the liver and the kidneys, with the occurrence of albuminuria. It has especial affinity for the nervous system and is found in very much larger amount in the brain and spinal cord than in the other tissues of the body, except, perhaps, the liver. In toxic doses, besides its effect upon the liver and kidneys, it destroys the red cells, dissolves the hæmoglobin, and as the result leads to hæmorrhages into the various tissues of the body.

Ague.—Arsenic is now recognised as the most powerful anti-periodic except quinine, and it may succeed where quinine has lost its power, and it is stated that the relapses are longer delayed under treatment by arsenic than by quinine. It is useful also in all affections of malarial origin, and especially in those malarial neuralgias the causes of which are often so difficult to determine. I do not know that any satisfactory explanation of its action in ague has been given, yet it may lie in the action of arsenic on the blood-cells in which the parasite of ague is found.

Diseases of the skin.—It is one of the stock remedies in all the chronic diseases of the skin, and especially in psoriasis. In some cases of chronic eczema it is found useful, but in many its use is disappointing, and in some it does positive harm. It is largely used in animals to give them a fine glossy coat, and in Styria and the Tyrol it is habitually taken by both men and women to produce *embonpoint* and fineness of complexion. Of recent years it has been largely advocated for the treatment of herpes zoster and post-herpetic neuralgias, but its use, I think, is disappointing.

For asthma it is a very old remedy and in certain cases almost a specific, being administered either by the mouth or by inhalation, as in the form of cigarettes. As a general tonic it is useful in a variety of conditions, provided it does not upset the stomach, but this can be generally avoided by giving it in small doses after food. Of recent years it has been largely used in affections of the nervous system, possibly because of the affinity which the drug shows, as already stated, for nervous tissues. Thus it has been given in epilepsy, but I think without much success. For neuralgias of all kinds it is an effective remedy. It is said to do good even in attacks of angina, but of this I am sceptical; but, having other more reliable remedies, I admit that my scepticism does not rest on much experience. As already stated, its chief use is in malarial neuralgias—e.g., brow ague.

The nervous disease for which it is most employed at the present time is chorea. It used to be recommended that small doses should be given and continued for some time. The result was not very obvious. Recently large doses have been advocated as soon as the patient comes under treatment, even as much as fifteen or twenty minims of the liquor arsenicalis three times a day even to a small child. It is often easy, if the drug be gradually increased, to reach amounts like this in the adult as well as in children, but it is somewhat startling to begin with such large doses from the first. However, I have myself tried this treatment in a number of cases and I have not seen any poisonous effects produced by it. Yet I cannot say that I am satisfied as to the immediate benefit which follows, nor can I endorse the statement that large doses will cut short a bad case within a few days. In a severe case of chorea which has been neglected and badly treated at home admission into a hospital is sure to be followed within a few days by marked improvement without the use of drugs at all, and if arsenic be administered as soon as the patient is admitted it becomes extremely difficult to know whether the improvement is to be referred to the drug or to the general management of the case. In private practice, where the cases are more closely under observation, it is quite possible that valuable information on this point may be forthcoming.

I do not propose to go into the question of acute arsenical poisoning, accidental or intentional. But on the subject of chronic arsenical poisoning of accidental origin, such as that acquired by arsenical papers and in other methods, a society of this kind would be likely to give information of great value and interest. The chief symptoms are general failure of health, loss of appetite and impaired digestion, with weakness of the eyes, thirst, salivation, cramps and colic, and in extreme cases emaciation, œdema of the face and body, perhaps albuminuria and ulceration in the skin. When symptoms of profound failure of health of this kind arise, for which no cause can be found, it is well to bear in mind the possibility of some accidental poisoning, of which, perhaps, arsenic is the most likely, sometimes accidental, as in the case of arsenical papers, sometimes intentional, with criminal intent, as in certain legal cases which we can all remember. Tolerance of the drug is easily established, so that the prolonged administration of the medicine necessitates the increase of the dose. The amounts which may be taken may be very large, as with the arsenic-eaters of Styria and the Tyrol. Cutting off the drug suddenly in such cases is said to produce grave symptoms of poisoning, which may be relieved when the drug is resumed. It would be interesting to know if any experiences of arsenic taking and its results can be communicated.

The prolonged administration of the drug is sometimes followed by mischievous, though very interesting, results, of which I may mention two—viz., arsenical pigmentation and peripheral neuritis.

Arsenical pigmentation is comparatively rare. Its colour is a dull brown. It may be general, but is more often irregular in distribution and sometimes more marked on exposed parts—e.g., the face and neck. When given to cure a skin disease—e.g., psoriasis—it may be limited to the seat of the eruption. Other skin eruptions are rare. Papular, measle-like rashes are described on the face and other parts of the body, and urticaria is comparatively common. Herpes zoster has been attributed by many writers to the drug, and pustular ulceration or even gangrenous eruptions have occurred after toxic doses. In these rashes the effect of idiosyncrasy is strongly marked. Thus marked pigmentation followed the taking of three minims only of the liquor arsenicalis three times a day for a week only, and in another case five minims had been taken three times a day for three weeks. Neuritis following arsenic is very rare and all cases of it should be recorded. It resembles lead poisoning and may appear as wrist-drop, though in advanced cases it may more closely resemble alcoholic neuritis and affect both legs and arms.[2]

TINCTURE OF DIGITALIS.

Digitalis is a drug that has no ancient history. It was used in the sixteenth century as an application to wounds, a vulnerary, and in the middle of the seventeenth century Culpepper writes that "it has been used by the Italians as a dressing for recent wounds and old sores, that it is recommended as a purgative, emetic, and deobstruent, and that it is beneficial in scrofula and scalded head, and that it has been found of late to cure divers of the falling sickness that have been troubled with it above twenty years." It was introduced into the London Pharmacopœia in 1721, and again omitted in that of 1746. It had been a popular remedy for some time in several parts of England for dropsy, and in 1775 was established as a good remedy for this condition by Withering, so that in 1788 it became a recognised article again in the Pharmacopœia. From this time it has been largely used in clinical medicine, but the more exact study of the drug dates from the middle of the present century. The investigation of its physiological

[2] Dr. James Taylor, in the course of the discussion, referred to the occurrence of neuritis following the administration of large doses of the drug in chorea.

Digitized by Google

action shows that in animals small doses increase the contraction of the heart, while in large doses the heart becomes irregular and finally stops in a condition of contraction. It appears to stimulate the cardiac and vaso-motor nervous system, as well as to increase the force of muscular contraction.

In man it first produces slowing of the pulse with a rise of blood pressure, regulating the heart's action and strengthening it. This sedative and regulating action upon the heart caused Bouillaud to designate it "the opium of the heart." With larger doses the pulse becomes rapid and the pressure falls, and in toxic doses the pressure falls still more, the heart becomes slow, and more and more irregular until it finally stops beating.

In therapeutics digitalis is chiefly used on account of its effect upon the heart, and especially where the heart's action is irregular and weak, for which condition it has become one of the stock remedies. Inasmuch as digitalis prolongs diastole and increases ventricular contraction it is just in mitral stenosis that it would appear to be chiefly indicated, for the lengthening of diastole would give the blood longer time to make its way through the narrowed mitral orifice, while the increased ventricular contraction would drive a larger quantity of blood out into the arteries, thus improving the general nutrition of the body, in which the heart would also share. It is, in fact, in mitral stenosis that it is found to be most serviceable, but it is almost as useful in mitral incompetence too, and this does not seem quite so easy to explain. These theoretical considerations would suggest that it was distinctly contra-indicated in aortic regurgitation, and it is true that it has to be given with greater caution in all aortic cases; yet, with caution and in smaller doses, I am satisfied of its usefulness even in aortic regurgitation. It has been stated that it is not a desirable remedy in cases of fatty heart. I do not agree with this, for I have given the drug frequently in all forms of weak heart and with great advantage, iron and digitalis being the most effective combination I am acquainted with for these conditions. It is especially useful in those cases of dilated and weak heart which are not uncommon in advancing years, but it is equally beneficial in other forms of weak heart, as, for instance, in the later stages of granular kidney, or even where the heart is enfeebled in the course of fevers.

In a very remarkable group of cases, that of acute myocarditis, of which I recorded an interesting series some years ago, the drug was very useful, but it exhibited in a marked degree the effect of the prolonged administration of the drug. At the time of commencing the treatment the heart was making a number of feeble beats, 150 or more in a minute, and digitalis was given with the view of decreasing their number and increasing their force. This it effectually did, and then after a time suddenly, without any symptoms at all in the patient to draw attention to the change, the pulse-rate fell, quite abruptly in some instances, to not more than 40 in the minute. The patient seemed in no way worse for this, and it would not have been discovered if the pulse had not been felt and counted. The drug was stopped, some stimulants given, the pulse rose to 70 or 80, and convalescence proceeded satisfactorily. In most of the cases, grave as the disease was, recovery took place but slowly and after a prolonged illness, as would be expected. Digitalis is also of great service in the alcoholic heart—i.e., the degenerate, dilated heart of drunkards, what is described popularly in Germany as the Bier-herz; but in this country we see it more often in spirit-drinkers. As a diuretic digitalis acts not directly upon the kidney, but indirectly through the circulation by its effect upon the heart and vessels. In the early stage of acute renal disease, when the tension is raised, digitalis is not a good remedy, yet it is not infrequently prescribed, though for a different reason. It is given when the urine contains some considerable amount of blood, with a view of checking the hæmorrhage, but I do not think it a useful remedy even then. It is in the later stages of acute nephritis or in chronic parenchymatous nephritis, when the tension is low, the powers feeble, and the heart weak, that digitalis does most good, and then it acts by bracing up the circulation. In granular kidney, again, it is not until the later stages, when the tension falls and the heart is weak, that digitalis is a remedy of real use; then it does good, for when the tone of the vessels is restored the patient is better. High tension in granular kidney is a part of the disease, and though a man would be better without a granular kidney at all, still if he has one he is better with high than low tension in his arteries, and it is, I believe almost as great a mistake to use depressing remedies to lower tension in the early stages of granular kidney as it would be to refrain from giving digitalis, on theoretical grounds, in the later stages.

Digitalis has been advocated as a hæmostatic. Its introduction for this purpose was due to the accidental discovery that digitalis in full doses caused contraction of the uterus and therefore checked metrorrhagia. Thus, as in the case of ergot, its use became extended as a remedy for hæmorrhage from other places, but I think there is little or no evidence that it has any action of this kind. It used to be advocated in the treatment of hæmoptysis on theoretical grounds—digitalis contracting, it was thought, the small arteries and capillaries, from which it was then supposed that hæmorrhage in hæmoptysis took place. As a matter of fact, it was found to do little of the kind, and now we know that if action could not be beneficial, but, if it had any action at all would probably be harmful, inasmuch as the hæmorrhage comes not from small vessels but from an aneurysm or rupture of a large vessel in the lung, so that if digitalis produced the effect desired and contracted the small arteries it would dam the blood up beyond the ruptured vessel and thus make the hæmorrhage greater. I suppose the giving of digitalis for hæmoptysis would in the early days have been called rational because physiological reason could be assigned, yet, tested at the bedside, it was found to be useless. Now the theory upon which it was based is known to be incorrect, the treatment ceases to be rational and the rational therapeutist does not use it for this purpose any more. In chronic bronchitis its use has been advocated also, but here again, I think, its only benefit is due to its action upon the heart.

In acute pneumonia digitalis was for a long time one of the stock remedies as it was for other fevers. Upon the temperature in such fevers digitalis has no effect, and in large doses it has long been given up as a dangerous and harmful remedy. Yet it is by no means without its use on account of the effect it has upon the heart. It is from the heart that so many cases of fever die and many of these may be saved by a judicious use of this drug. For myself however, I prefer the citrate of caffeine, which, associated with strychnia, I believe to be one of the best combinations where the heart is falling in fevers. The effect of digitalis upon the falling sickness is referred to in the early description of the drug given by Culpepper, which I have quoted, and quite recently Dr. Gowers has advocated the use of this drug in epilepsy in combination with belladonna, as it seems to increase the effect of the bromides. A few years ago full doses of the infusion of digitalis were advocated in delirium tremens. The discovery was made by accident by Dr. Jones of Jersey, to one of whose patients an ounce of the fresh infusion of digitalis was unintentionally given, but so far from doing harm it did good, and subsequent experience led Dr. Jones to advocate this mode of treatment strongly. I have not used it myself much, for most cases of simple delirium tremens get well with general treatment and little medicine. It will be interesting to know what the personal experience of the society is on this point.

There is a general opinion that the best preparation of the drug is an infusion in cold or warm water, but that which in most common use is the tincture, the only objection to which is that its strength appears to vary somewhat. The different substances obtained chemically from digitalis and included under the term "digitalin" are not popular on account of the uncertainty of their composition and action. There appear to be at least four different glucosides, all of them very poisonous and with a somewhat different action as they occur in the different common forms of digitalin in different proportions: thus Homolle's digitalin consists almost entirely of Schmiedeberg's digitalin; Nalivelli's crystallised digitalin consists, on the other hand, almost entirely of Schmiedeberg's digitoxin. Until the composition and activity of these different digitalins become more constant I think we should do well to abide by the well-tried preparations—viz., the tincture and the infusion.

Digitalis is slowly absorbed and slowly eliminated; it is thus cumulative in action, so that it is wise to watch the effect of the drug. It may be necessary to suspend its action from time to time. Yet this is by no means always necessary, for I have had patients continue to take the tincture of digitalis for months together with nothing but advantage. However, the ill effects of digitalis may appear sometimes quite suddenly and without warning.

Digitized by Google

ve already referred to the sudden drop which may take ace in the pulse, and another symptom produced by the ug is vomiting. The sickness, which is often spoken of as ardiac vomiting" because it is so often met with in rdiac cases, is in many instances due to the digitalis, for soon as the drug is stopped the symptom passes away and es not return unless the drug be given again. The influ-ce of idiosyncrasy is as well marked with digitalis as it is th the other drugs I have been speaking of, and in some stances hardly the smallest dose of the drug can be erated. I do not know, however, of any peculiar effect at idiosyncrasy causes.

Time has not permitted me to consider all the drugs placed on the list by your committee. The rest must be reserved other occasions. In preparing this paper I have had to view my own experience with the common remedies and consider the conclusions to which it leads me. This has oved a task not only interesting but useful, and I trust that hers may have found it so too.

Wimpole-street, W.

EIGHTEEN CASES OF INDURATED PSEUDO-CHANCRES.

ARTHUR SHILLITOE, M.B. CAMB., F.R.C.S. ENG.,
REGISTRAR TO THE LONDON LOCK HOSPITAL.

AM indebted for the following examples of this interest-lesion to the observations my father has made on cases urring in his private practice during the last few years. Hutchinson, in the London Hospital Reports for 1866, cribed twelve such cases, which he has preferred to call apsing chancres. The word "relapsing" seems to imply urrence in the original site. This is certainly the usual rse, but Mr. Hutchinson, in speaking of these lesions in the tsomian Lectures for 1886, said: "They occur to those have had syphilis, and usually, but not invariably, the site of former chancres." Again, in his work on philis,[1] in speaking of second infections of syphilis Hutchinson records the case of a man who came to him h a "well-characterised" chancre "which he made no bt he had caught by contagion, although it was only e months since a previous one, and he was not yet rid of secondary symptoms." The second sore was on quite a erent part of the penis. On the same page he quotes a ely resembling case under the care of Mr. Allingham. Hutchinson says: "I do not know what to make of these es of second chancres occurring before the first syphilis is ed and not on the site of the original chancre. It is sible, after all, they are only examples of relapsing or haps satellite sores."

gain, the word chancre in the term "relapsing ancres" seems to imply a greater resemblance of these ons to the initial sore of syphilis than is justified by course of after events. Microscopically it is, perhaps, ossible to diagnose an indurated pseudo-chancre from the infecting sore. But from this point all resemblance es. Mr. Hutchinson[2] says "they never lead to any-g in the way of secondary symptoms." Against this statement M. Fournier, in the *Archives Générales de ecine*, 1868, says they are often followed by secondary tertiary symptoms. The examples I have quoted below rather to bear out Mr. Hutchinson's statement. Those s in which secondary symptoms occurred after the arance of the pseudo-chancre were all cases in which pseudo-chancre appeared early in the disease—that say, within a few months of the primary infection—leading one to suppose that the presence of a do-chancre influenced in no way the occurrence of ndary symptoms. Bumstead, in the last edition of his on Venereal Diseases, calls these lesions "recurrent rations." The same objections seem to me to hold with d to the word "recurrent" as in the word "relapsing." have called these new sores pseudo-chancres simply d seem to imply some relation to the soft or non-ting sore or chancroid, besides omitting the one inal symptom, induration, so that I have preferred to adopt the name given to these lesions by M. Fournier—namely, indurated pseudo-chancres.

[1] Hutchinson: Syphilis, 1889, p. 467.
[2] Loc. cit., p. 121.

CASE 1. *Appearance of indurated pseudo-chancre without any known cause ten months after original infection.*—In June, 1892, this patient had several indurated sores at the corona and some slightly indurated inguinal glands. The sores appeared five weeks after infection, which took place seven weeks previously, during which time he had had no treatment. He was now treated with mercury, and in a month the sores had all healed, leaving some induration. He was slightly salivated. In August there was an ulcer on the lower lip, and also on both tonsils. In November the throat was still red, though not ulcerated, and the patient complained of weakness. In Feb. 18th, 1893, the throat, which had been quite well, was again red and congested. There was a small spot on the penis. In March all the original sores had again become indurated. The patient said there had been no fresh intercourse. The inguinal glands had not re-indurated; there was no eruption and the throat was still congested. In April the induration had almost disappeared, but the patient again complained of feeling weak. In June there was still some slight induration on the left side of the corona, but no other symptoms. In October there were no symptoms.

CASE 2. *Reappearance of indurated pseudo-chancre five times within eighteen months of the primary infection.*—In June, 1890, this patient had a sore on the penis, which had been irritated by some caustic application. The inguinal glands were hard and discrete. It was at this time two weeks since infection. He was given two-grain pills of mercury and chalk three times a day and was readily salivated. In four weeks the sore had healed and the (?) induration was much diminished, and in August the sore and all induration absolutely disappeared. In October the induration in the sore returned and disappeared again in January, 1891; there was then no salivation and no other symptoms. In March the induration was as marked as when first seen, and the patient was still taking the mercurial pills. In April the induration, which had disappeared, had again returned. In June there were no symptoms. In July the patient stated that he had had intercourse regularly and the induration had returned. In October the sore was again red and swollen after intercourse. In January, 1892, there were no symptoms. Since the previous June he had been taking potassium iodide. He had eczema badly, to which he had long been liable. In February the eczema improved under arsenic and there were no other symptoms.

CASE 3. *Reappearance of indurated pseudo-chancre twice within twelve months of the original infection.*—In July, 1892, this patient, aged twenty-six, had a single sore on the glans penis and some indurated inguinal glands. The last intercourse was five or six weeks previously. Mercurial treatment was employed. In August the sore had healed, but the induration and the glands persisted; in September there was ulceration of the left tonsil; in November the throat was well; and in January, 1893, there were no symptoms. In May, however, the left tonsil was again congested and red. The palate had been ulcerated, but by the end of the month there were no symptoms. In June the induration in the old cicatrix and in the glands had returned, but by October the induration had entirely disappeared and there were no other symptoms. In December there was a return of the induration in the old cicatrix; in January, 1894, the induration softened and the patient was much better; in April the induration still persisted, especially in the inguinal glands. In July, contrary to advice, he married. He had lately been taking a mixture containing mercury and potassium iodide. In March, 1895, there was still some thickening in the old cicatrix and he had patches of psoriasis in several places. He was ordered to try Donovan's solution. In May the psoriasis was not increasing.

CASE 4. *Appearance of indurated pseudo-chancre seven years after the primary infection.*—In 1878 this patient was treated for an indurated sore and indurated inguinal glands. He said that he never had any further symptoms. In November, 1885, he had a single indurated sore and very indurated inguinal glands. The sore appeared one week after infection, which took place a month previously. He was put on mercury. In December everything had cleared up. There were no symptoms. He was instructed to continue the treatment for some time longer. In March, 1889, the patient had had no further symptoms.

CASE 5. *Appearance of indurated pseudo-chancre six years after the original infection.* —In February, 1885, this patient

Digitized by Google

had a single indurated sore on the penis and indurated inguinal glands. It was two months from the date of infection. Mercurial treatment was employed. In March he was salivated and the induration of the inguinal glands was more marked. In April there were secondary throat symptoms, in May the throat was well, and in August there were no symptoms. In March, 1886, a suspicious spot at the angle of the mouth and on the lower lip was noticed. In July there were no symptoms, but the patient had a gleet. In November he had buboes after gonorrhœa. During 1887 he had an indurated inguinal gland, but no other symptom. In July, 1891, the patient stated that he had a patch of inflammation sixteen days previously on the old cicatrix, which was then indurated. In September this had nearly healed, and in December all was perfectly healed under mercury, and there were no further symptoms.

CASE 6.—*Appearance of pseudo-chancre seven years after the primary infection, together with a relapse of rupia.*—In July, 1889, this patient had a return of induration, which was very decided in a cicatrix at the frænum, which had been ruptured since he had a hard sore seven years before. The last intercourse was in February, 1889. Some old scars, the result of rupia, which he had in the previous attack, when he took mercury for three months, were beginning to get red and swollen. Mercurial treatment was employed. In August the induration continued and also in the rupial scars. In October the rupial scars were all quieting down. Every one of them became red, thickened, and raised above the surface. The old cicatrix on the penis was still very indurated and a hard, ridge-like band extended from the frænum to the side of the corona. In May, 1890, there was still some induration in the cicatrix, and the rupial scars had all become pale and soft. In September mistura biniodidi was employed. In November there was some eruption on the forehead. In December iodide of potassium was administered, and in January, 1891, the eruption had all gone. In May there were no symptoms.

CASE 7. *Appearance of indurated pseudo chancre ten years after the original infection.*—This patient stated that in 1880 he had a sore on the penis, which was followed by secondary symptoms. In June, 1890, he had a single sore on the penis; this appeared four days after the last intercourse. The sore was treated with iodoform, but in spite of this it extended and indurated, so the patient was given mercury, and by the end of the month the sore was, though large and circular, commencing to clean. The gums were tender. In July the sore was still extensive, with an indurated base, but healing in part. In July, 1893, the patient stated that he continued with the mercury for some time and nothing followed; he at that time had an indurated chancre at the meatus. He was placed under mercurial treatment. In August the sore was spreading and sloughy. Iodoform was ordered as well as mercury. In November the sore was clean, not spreading but not healing. Potassium iodide was administered instead of mercury. In May, 1894, the patient stated that after his last visit the sores soon improved; he continued taking the iodide mixture up to January, 1894. About three weeks previously he had lived freely for a few days and very shortly after this he noticed an ulceration inside the mouth in the region of the upper left molar teeth. At the time he had a tertiary ulceration extending between the upper and lower jaws. He was instructed to resume the iodide mixture. In March, 1895, there was tertiary ulceration over the spine, which improved during the month under the administration of fifteen grains of iodide of potassium three times a day.

CASE 8. *Appearance of indurated pseudo-chancre nearly four years after the original infection.*—In January, 1888, this patient had an indurated sore, which was followed by doubtful secondaries. He stated that he certainly had a bad sore-throat. In November, 1891, he had a single sore near the frænum ten days from the last intercourse. The sore was indurated and so were the inguinal glands. Mercurial treatment was employed. Within a month all the induration disappeared from the chancre but not from the glands. In December the glands were marbly. In August, 1892, there was herpes on the penis, but there were no further symptoms.

CASE 9. *Appearance of indurated pseudo-chancre four years after infection.*—In 1888 this patient had a sore on the penis, which was followed by secondary symptoms. In June, 1892, he had a single sore on the penis, which came on immediately after intercourse one month previously. There was no definite induration, but one enlarged inguinal gland. The treatment was mercurial. At the end of the month the sore was indurated and not healing and the inguinal glands were enlarging. By August everything had cleared up. In November the patient had herpes and in December there were no symptoms.

CASE 10. *Appearance of pseudo-chancre twice within twelve months of infection.*—In February, 1892, this patient had two sores, one at the root of the penis which was indurated, and the other looking like herpes. The last intercourse was three weeks previously. Mercurial treatment was employed. In March the sore at the root of the penis healed, leaving a large indurated cicatrix. During the month the induration broke down and then healed again. The patient was slightly salivated. In May ulceration of the right tonsil was present. In August both tonsils had become ulcerated and the patient was very weak. In September the throat and tonsils were affected. In December the throat was well; the original chancre at the root of the penis was again red and swollen. There was a patch of psoriasis on the head. In January, 1893, the induration had nearly disappeared. In February, after intercourse a week previously, the chancre was again hard and inflamed. In March there was a circular ulcer on the palate. In May the patient was going on well, but by the end of the month complained of general rheumatoid pains, which were relieved by salicylates and iodide of potassium. During July he had continuous headache, great weakness, and relaxed throat. In October there was a return of the rheumatoid pains, an ulcer on the left tonsil, and a pustular eruption over the cicatrix on the penis. He had been living freely. In December the throat was sore and induration of the chancre was still present. In January, 1894, the throat was better and there was no ulceration. Iodide of potassium was ordered.

CASE 11. *Appearance of indurated pseudo-chancre within four months of the primary infection.*—In January, 1885, this patient had a single indurated chancre on the penis and indurated inguinal glands. The last intercourse was in December, 1884. He was treated with mercury, and this lessened the induration. In March the induration had almost disappeared in spite of the patient having been somewhat negligent with the treatment; some days, he said, he had taken no mercury. In April there was a return of the induration in the cicatrix of the original sore. In November he had had no further symptoms, but had two small sores after fresh intercourse.

CASE 12. *Appearance of indurated pseudo-chancre a year and a half after the primary infection.*—In November, 1888, this patient had an indurated sore on the penis, which was followed by secondary symptoms. In April, 1890, there were a small indurated sore on the penis and indurated inguinal glands. The last intercourse was seven weeks previously. He was treated with mercury and was slightly salivated, but the sore speedily healed. In September there were a deep ulcer on the right tonsil and superficial ulcers on the pharynx. By July, 1891, the patient had not progressed in an altogether satisfactory manner; he would not persevere regularly with the treatment and had fresh sores on the penis, which during the next month healed under mercury.

CASE 13. *Appearance of pseudo-chancre four years after infection.*—In January, 1888, this patient had an indurated sore at the frænum and indurated inguinal glands, it being four weeks since the last intercourse. Mercurial treatment was employed. In February the induration was softening. In March the gums were tender, the induration was less, there were commencing roseola and indurated cervical glands. In April there was roseola on the forehead and back and the throat was tender. In May there was no salivation, the throat, which had been tender, was well; the roseola had disappeared; and with the exception of the indurated inguinal glands there were no symptoms. In June the throat was ulcerated. In January, 1889, there were two sore places in the mouth, otherwise the patient was going on well. In August there were two small spots on the forehead. In October, after intercourse nine days previously, there was a sore on the scrotum and the left testis was swollen. The sore healed in about three weeks on the biniodide mixture. In April, 1890, there were no symptoms. In March, 1893, after intercourse nine days previously, there was a small indurated sore on the penis which in a week healed under mercury and the induration was much diminished. In April everything cleared up. In October the patient had herpes.

CASE 14. *Appearance of indurated pseudo-chancre twenty-two months after infection.*—In January, 1894, this patient, aged thirty, and rather delicate-looking, had a single indurated sore on the left side of the corona with slightly

Digitized by Google

indurated inguinal glands. This appeared three weeks after infection, which took place one month previously. He had a very long prepuce. Mercurial treatment was employed, and in a week the sore was nearly healed. In February he was troubled with diarrhœa and at the end of the month the induration again increased after two or three emissions. In April the induration was more marked; he was still troubled with diarrhœa. In May the induration had nearly disappeared. In September there were no symptoms. In October the throat was sore. In January, 1895, he had taken a fresh cold and the throat was again sore. In February the post-cervical glands were enlarged and there was an eruption on the scalp; he had taken no mercury for a month. In April there were secondary throat symptoms and nodes on the tibiæ, the post-cervical glands were again enlarged, and he had general rheumatoid pains. In May there was a general improvement. In June he again took cold; the throat was again red and congested, the anterior cervical glands were enlarged and indurated, and there was an eruption on the forehead and vertex. In September the glands cleared up in about two weeks under treatment, but he had taken a fresh cold and they were again much enlarged. In October there was a small pustular ulcer on the forehead, also a relapse of the original chancre on the penis, which was indurated and resembled a typical infecting sore. The inguinal glands were slightly indurated. There had been no fresh intercourse. In November, under iodide of potassium, the ulcer on the forehead disappeared in a few days.

CASE 15. *Appearance of pseudo-chancre six years after infection.*—In June, 1894, this patient had a return of induration in the site of an old chancre which he acquired six years previously, when he took mercury and iodide of potassium for twelve months. He stated that for some time he had had a secondary affection of the tongue, but no other symptoms. He was much troubled with priapism, and he said that there had been no intercourse for two years. The present induration had only been present for a few days. In August the induration was diminishing under mercury.

CASE 16. *Appearance of indurated pseudo-chancre twice within ten months of the primary infection.*—In December, 1893, this patient had a single sore near the frænum with enlarged inguinal glands three weeks since infection. He was treated with iodoform. In January, 1894, the sore had almost healed, but the glands were very indurated. Mercurial treatment was employed. In February one gland was suppurating. In May the bubo had nearly healed, but he had several sores, some of which were indurating. He had had fresh intercourse a week previously. The sores improved under treatment, but the induration at the frænum persisted. The gums were tender. In August there was a return of the induration in the old cicatrix. In October there was another relapse of the induration. He had been living freely, had not gone on with the treatment, and stated that he had had no intercourse for six months. The sore was spreading and inclined to be phagedænic. In November the phagedæna was arrested only after considerable trouble by the free use of nitric acid, and by the end of the month it was all healing up soundly.

CASE 17. *Appearance of pseudo-chancre twenty-five years after infection.*—Twenty-five years previously this patient had syphilis. Two or three years later he had herpes, which lasted for nine months. He had also had diabetes, which irritated the prepuce, causing congestion, rawness, and adhesions. In August, 1894, there was a small sore beneath the edge of the prepuce near the frænum. This appeared at first as a slight thickening of the preputial edge. There was no history of infection. The glands were not enlarged. The induration had existed for five weeks and was extending. Mercury was employed. In October the preputial adhesions were broken down and the induration had become smaller. Later in the month a fresh separation was necessary, and the sore became swollen and thickened, like an infecting chancre. In November the induration had almost gone, but the prepuce was very tender and irritable.

CASE 18. *Appearance of pseudo-chancre within four months of original infection.*—In July, 1894, this patient had gonorrhœa, which commenced about one month previously. A week prior to date the underneath part of the urethra became swollen and a spot appeared on the scrotum. When first seen he had apparently four or five chancres, together with some induration of the inguinal glands. Mercurial treatment was employed and suitable treatment for the gonorrhœa. Within a week the induration was decided, and at the end of the month the sores had healed. In August one sore was still indurated. In October the patient had been under treatment in the north. The one sore soon disappeared, but at the end of September the induration had reappeared in the original site. There had been no eruption on the skin, but he had a very badly ulcerated throat. In November the throat was well, but he had been salivated. In January, 1895, a slight eruption appeared on the forehead; the mercurial treatment was continued. In May there was some enlargement of the right tonsil. In August the patient was going on well. In December he was still progressing satisfactorily.

In the above-quoted cases it will be noticed that the indurated pseudo-chancres appeared at the following intervals after the primary infection: Case 1, in ten months; Case 2, in five months, ten months, eleven months, fourteen months, and seventeen months; Case 3, in twelve months; Case 4, in seven years; Case 5, in six and a half years; Case 6, in seven years; Case 7, in ten years; Case 8, in three and three-quarter years; Case 9, in four years; Case 10, in eleven months and thirteen months; Case 11, in four months; Case 12, in one and a half years; Case 13, in four years; Case 14, in twenty-two months; Case 15, in six years; Case 16, in nine months and ten months; Case 17, in twenty-five years; and Case 18, in four months. Mr. Jonathan Hutchinson in the London Hospital Reports for 1866 described a series of cases of relapsing chancres and found that the relapses occurred within a short time of the original infection. In the *Archives Générales de Médecine*, 1868, M. Fournier also described a series of cases of this nature which he called "indurated pseudo-chancres"; he, too, found that the pseudo-chancres occurred within a short interval of the primary infection—viz., in the second month 7 cases, in the third month 4 cases, in the fourth month 3 cases, in the fifth month 3 cases, in the sixth month 2 cases, in the seventh month 1 case, and in the tenth month 1 case. Bumstead says "relapsing indurations," as he calls these lesions, may occur any time up to the tenth year. The cases I have given seem to satisfactorily show that there is no limit to the time in which these indurated pseudo-chancres may appear.

In Cases 1, 6, 14, 15, 16, and 17 intercourse as a cause of the reappearance of the chancre was denied by the patients. In Cases 3, 5, 11, and 18 there was no history either way. In Cases 2, 4, 7, 8, 9, 10, 12, and 13 the reappearance of the chancre followed on intercourse. In Case 2 the patient had had intercourse regularly. In Cases 4, 7, 8, 9, 10, and 13 the indurated pseudo-chancre appeared within a short time after intercourse—viz., Case 4, within a week; Case 7, within four days; Case 8, within ten days; Case 9, immediately; Case 10, within a week; and Case 14, within nine days. In Cases 1, 5, and 17 the glands were not affected by the new sore. In Cases 3, 4, 8, 9, 12, and 14 the inguinal glands re-indurated. Case 6 showed relapse of the rupia and tertiary symptoms, the patient stating that the last intercourse was six months previously. In Cases 10, 12, 14, and 18 the indurated pseudo-chancres appeared quite early in the disease; secondaries appeared, probably the result of the primary infection, and not influenced in the least by the presence of the pseudo-chancres. Cases 8, 9, 13, and 17 suffered eventually from herpes, to which, according to Mr. Hutchinson, syphilitic subjects are liable.[3] In Cases 2, 4, 11, and 16 the symptoms of syphilis in the primary attack were only the presence of an indurated chancre and indurated inguinal glands. In Cases 1, 3, and 10 the pseudo-chancre appeared while the patients were under treatment for the original sores. Case 2 lived very irregularly, all five relapses occurring while still under treatment. In Case 6 the original attack was severe, but the patient appears to have been only treated for three months. Case 11 took treatment irregularly. Case 14 was most careful in following out treatment. Case 15 was treated in the original attack for twelve months with mercury and iodide of potassium. Case 17 was due (?) to the irritation caused by an adherent prepuce. There is a case of relapsing chancre recorded by Mr. W. Robinson[4] in which mercury did no good, but in which circumcision cured the relapsing induration and relieved the patient of his phimosis.

The effects of treatment and predominant symptoms in these cases.—The treatment of the original attack of syphilis consisted of small doses of mercury such as hydrargyrum cum creta, two grains, three times a day. In Cases 13 and 16 the

Digitized by Google

gums were tender; Cases 1 and 10 were slightly salivated; Case 5 was salivated; and Case 2 was easily salivated. And in all these cases, with the exception of Cases 2 and 16, it should be noticed that the predominant symptom was some affection of the throat or mouth or both. In Cases 1, 3, 5, 8, 12, and 15 though the mouth or throat were affected there was no eruption on the skin. In Case 10 the throat and mouth were badly affected; there was a patch of psoriasis on the scalp after the first relapse, and later general rheumatoid pains. In Case 13 the throat and mouth were affected. An evanescent roseola appeared on the forehead and back. In Case 14 the affection of the throat was very obstinate. There was no rash on the skin, but nodes on the tibiæ and frequently relapsing enlarged cervical glands. Later there was a pustular eruption on the forehead, which rapidly cleared up under iodide of potassium. In Case 15 there was obstinate secondary affection of the tongue. In Case 18 the throat was affected. There was slight erythema on the forehead. John Hunter,[5] in 1786, said: "It often happens that after chancres are healed and all the virus gone is the cicatrices ulcerate again and break out in the form of chancres." ..... "They appear to be a consequence of a venereal complaint having been there, as they seldom attack those who never had gonorrhœa or chancres." ..... "I know one case where they broke out regularly every two months exactly to a day." In the *Archives Générales de Médecine* for 1863 Diday published an account of 25 cases of what he called "second attacks of syphilis." He had personally seen 20 of the cases All had had syphilis, the symptoms of which had all cleared up except in a few where some tertiary symptoms were present. In 14 of these cases the only symptom of re-infection was the indurated chancre. He explained this by saying that the nearer the relapse came to the original attack the more feeble was the effect, yielding only a chancre, and *vice versâ* the longer the interval the greater the probability of secondary and tertiary symptoms appearing. The cases I have quoted do not agree with Diday's experience, for Case 4 relapsed seven years after the primary infection and had no further symptoms; Case 5 relapsed in six and a half years and had no further symptoms; Cases 6 and 7 relapsed in seven and ten years respectively and had no secondary symptoms; Cases 8, 9, and 13 relapsed in three and three-quarter years, four and a half years, and four and a quarter years respectively, and had no further symptoms except herpes; and Cases 15 and 17 relapsed in six years and twenty-five years respectively. These last two cases are unfortunately incomplete. Might we not consider fourteen at least of the twenty-five cases given by Diday as instances of indurated pseudo-chancres and not as examples of reinfection?

In 1874 Mr. Gascoyen read a paper before the Royal Medical and Chirurgical Society on Eleven Cases of Syphilitic Reinfection. Mr. Gascoyen thought that the induration at the base of the chancre is as pathognomonic of general syphilitic contamination as are the eruptions, and consequently would have us believe that in Case 1 of his series the patient was reinfected in 1867, 1868, and 1870, and that between 1870 and 1874, during which time he had married and had two healthy children, he was reinfected two or three times. His health throughout was good. The original chancre was in 1863; the relapses were not followed by secondaries. Case 3 was only under observation a fortnight, the only evidence of reinfection being the indurated chancre. Case 4 recovered without treatment. Case 5 was only under observation one month, the symptoms of reinfection being the indurated sore and enlarged glands. Case 9 is said to have recovered without treatment; he refused to take mercury, as he wished to see whether a man could have syphilis twice. The older writers on syphilis taught that a man might have syphilis over and over again.[6] Was this from their having observed examples of the lesion under discussion, or from their failure to comprehend the necessity for a long course of treatment during the original attack? In 1859 Ricord said "the indurated chancre never relapses and that the syphilitic diathesis is no more reproduced than any other kind of diathesis." In 1872 he qualified this by saying that, though possible, like a second attack of variola, yet in his long experience he had never come across an instance of a man having an indurated sore and secondary syphilis more than once in his life, and that so long as the patient is suffering under the syphilitic diathesis arising from an indurated chancre he cannot have another indurated chancre, nor while a man has secondaries can he have a chancre of an indurated character. Mr. Gascoyen and Follin, in that they regarded the induration of the chancre as pathognomonic of syphilis, would have regarded all the cases I have quoted as examples of re-infection. In 1873 Mr. Gascoyen said "that the presence of induration about a sore shows, in the first place, that the system was free from syphilis when the induration was acquired; and, secondly, it shows that the patient is at the time under the influence of syphilis." And again: "The formation of an induration in a man who has previously had syphilis is a proof that he has recovered from the previous attack." In my cases Nos. 1, 6, 14, 15, 16, 17, and 18 denied all possibility of re-infection; and in Cases 1, 2, 3, 12, 14, 16, and 18 the re-indurations occurred whilst the patients were still under treatment for the primary attack. Mr. Henry Lee said that a man might have syphilis twice, but that so long as he remains syphilitic he is incapable of being re-infected and considered the amygdaloid condition of the glands as the great proof that a person was still syphilitic unless he had passed into the tertiary stage. In my Cases 3, 12, and 14 the inguinal glands re-indurated with the relapse of induration in the chancres, yet the patient in each of these cases was still under treatment for the original attack. In the Harveian Lecture for 1877 Mr. James R. Lane said that a man does not contract a second indurated sore so long as he is under the influence of the syphilitic diathesis. Mr. Venning[7] said that when the indurated glands had disappeared, then and then only was the patient free from syphilis and again in a condition for re-infection. Mr. Hutchinson says that for a man to have a second attack of syphilis it is necessary that he should be cured of the first in so far as it is a blood disease, and insomuch as he considers the lesions under discussion occur within a short time of the original infection he does not allow that these cases are examples of re-infection. Further, he says that cases of relapsing chancre are rare, though they are infinitely commoner than second attacks of syphilis. Ricord, Sigismund, and Bumstead[8] all lay particular stress on the amygdaloid condition of the inguinal glands as evidence of syphilis. On reference to my cases it will be seen that in Case 4 the glands became re-indurated seven years after the original attack, in Case 8 three and three-quarter years, and in Case 9 four years, with no further symptoms of syphilis except herpes. Drysdale[9] said that for twenty years he had looked for cases of reinfection and found none. Mr. Edward Cotterell, in his paper read before the British Medical Association in 1895 on Syphilitic Antitoxin, says: "One attack of syphilis confers immunity from subsequent infection upon the individual affected, the exceptions to this rule being so rare that they may be entirely disregarded." In THE LANCET of March 10th, 1877, Mr. Henry Smith recorded a most interesting case which occurred in King's College Hospital. A man aged sixty-five years was admitted for epithelioma of the penis. Seven years previously he had contracted a chancre, which was followed by secondary symptoms. He was treated by a druggist and the chancre healed. It relapsed one year later in the original site after a drinking bout. It healed in three weeks and has relapsed four or five times since, always after heavy drinking. Sometimes he was treated, at others not. Secondary rashes appeared four or five times, not always as a direct sequence of the chancre. There had been no fresh intercourse. This case seems to illustrate two points so strenuously insisted upon by M. Fournier: (1) pseudo-chancres are often followed by secondary symptoms; (2) pseudo-chancres are especially prone to occur in patients who are careless or negligent about treatment; and (3) it bears out Sir William Gull's well-known aphorism, "If you wish to keep your syphilis preserve it in alcohol."

May these pseudo-chancres be considered as in any way analogous to the relapsing inflammations of Sir James Paget? Writing of these Sir James Paget says: "Relapsing inflammations are due to the disturbed or interrupted nutrition, not only of the tissues deteriorated in previous inflammations, but of the new materials that were formed among them." M. Fournier suggested that we should consider these lesions

Digitized by Google

as belonging to constitutional manifestations of a special form, having their origin and their cause in the primary infection and absolutely independent of all further contagion. Taking into consideration how seldom these pseudo-chancres are followed by secondary symptoms (Mr. Hutchinson[10] says never), and the cases I have given agree with this except Cases 10, 12, 15, and 20, in which the relapse occurred quite early in the disease, thereby seeming to show that the presence of the relapses did not influence either way the onset of secondary symptoms, it seems that an explanation of these lesions might be found in combining the theory of M. Fournier with that of Sir James Paget on relapsing inflammations—viz., that we should consider these pseudo-chancres as due to the disturbed or interrupted nutrition of the new materials that were formed among the tissues deteriorated in the previous inflammations and that they owe their peculiar likeness to the infecting sore because they had their origin and their cause in the primary infection and are now absolutely independent of all further contagion.

The cases I have quoted seem to me to show: 1. That the indurated pseudo-chancre may appear at any interval after the initial lesion. 2. That if the interval of immunity has been a long one the indurated pseudo-chancre is not followed by secondary symptoms. 3. That if the interval between the appearance of the pseudo-chancre and the original sore is a short one, the onset of secondary symptoms is not influenced in any way by the new sore. 4. That these lesions may arise spontaneously quite apart from fresh intercourse. 5. That if the history be not known it is almost impossible to diagnose the pseudo-chancre from the initial lesion of syphilis. 6. That the predominant secondary symptom in the original syphilitic attack in the cases I have quoted was some affection of the mouth and throat rather than cutaneous eruptions. 7. That the presence of induration in a sore, accompanied it may be by induration of the neighbouring lymphatic glands, does not necessarily imply that the individual has been re-infected with syphilis. 8. That these lesions yield rapidly to mercurial treatment or even spontaneously disappear. 9. That these pseudo-chancres are not syphilitic, though occurring in individuals who are or have been the subjects of syphilis. 10. That, as the case I have quoted under the care of the late Mr. Henry Smith shows, these lesions may eventually terminate in malignant disease. 11. As Mr. Hutchinson has pointed out:[11] "The knowledge of the facts as to the recurring chancres is of very great importance, since without it very serious mistakes may occur, not only as regards treatment, but in reference to social and medico-legal questions."

Frederick-place, Old Jewry, E.C.

ON CONSTIPATION AND DIARRHŒA.[1]

BY T. LAUDER BRUNTON, M.D., F.R.S.,
PHYSICIAN TO, AND LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT, ST. BARTHOLOMEW'S HOSPITAL, ETC.

THE subject of Constipation and Diarrhœa is one that is interesting to every medical man because, I suppose, there are no other ailments for which he is so often consulted. Constipation especially is so exceedingly common in civilised communities that I think we ought hardly to look upon it as a disease. We find it amongst the strongest, the healthiest, and the longest lived of our people, and although they suffer from it and therefore ask for aid from medical men it is probable that we should regard constipation really as the reaction of a healthy organism to unfavourable surroundings. The unfavourable, or unnatural, surroundings may be said to be, too soft food, too little water, or too little exercise. There are no doubt many other conditions which tend to bring about constipation, but these three may, I think, be looked upon as the chief factors in the production of chronic constipation. Primitive communities take food which is not only rather hard and generally imperfectly cooked but leaves a considerable amount of indigestible residue. In our school-days we used to read how Cæsar and his troops carried with them little hand-mills and bags of corn or of wheat. The corn or wheat was put into the hand mill and roughly ground. In this way the grain was imperfectly broken up and so taken by the soldiers. Amongst uncivilised communities at the present day it may be simply pounded. In civilised countries, however, we have mills which not only grind the corn very finely, but separate the outer and more indigestible part of the grain from the starch which constitutes the interior of the grain. We thus get rid, by the perfection of our machinery, of those parts of the grain which would leave in the bowel undissolved residues and which would act thereby as a mechanical stimulus to the peristaltic action of the bowels. Similarly in regard to fruits and vegetables; we are accustomed to take them not in their crude state, but well cooked, and if there are any indigestible parts either in the vegetables or in the fruits these are generally removed.

Soft food, then, is one of the first causes of constipation, and in trying to treat constipation one of the first means to which we have recourse is to bring our patients back to the conditions under which less civilised nations usually live. We advise them to take bread either consisting of whole meal or with a greater or less admixture of bran. We advise them to take vegetables in abundance, either cooked, such as cabbage, spinach, brocoli, Brussels sprouts, cauliflower, carrots, turnips, parsnips, and the like, or we advise them to take vegetables such as tomatoes, celery, and so on, raw as well as cooked. In America it is very common indeed for people to begin or finish their breakfast with a slice or two of raw tomato or a slice or two of melon, and these fruits very often are sufficient to keep the bowels open. In this country we not infrequently recommend patients to take in the morning a raw apple or two, suck an orange or two, or eat a fig on an empty stomach before breakfast, and here also we very frequently find that we get the desired result. One of the most common of the fruits we prescribe is stewed prunes, and frequently these keep the bowels open, or a stewed or roasted apple or two may do so also. Many patients, however, find that even stewed prunes are insufficient to keep the bowels open, and in such cases one may succeed in getting a regular movement by simply taking some senna leaves, tying them in a muslin bag and putting them into the pan beside the prunes to be stewed. This very simple plan has in some cases that I have had under treatment succeeded when the ordinary method of just recommending stewed prunes has proved insufficient.

Fruits also contain, as a rule, salts of vegetable acids and many of them contain sugars, and both these salts and the sugars are of importance as laxatives. In the case of a fig, we find that there are three kinds of laxative properties: there is (1) the mechanical irritation due to the altogether indigestible seeds; (2) the stimulus given by the vegetable salts contained in the fig; and (3) the stimulus given to the bowel by the sugars.

Sugars in themselves are useful laxatives, and golden syrup, honey, or still better, perhaps, the old-fashioned black treacle, are very useful laxatives, and they may be given—at least the syrup and the treacle may be given—along with oatmeal porridge in the morning. Honey, treacle, or syrup may be given spread upon bread or the latter two may be mixed with the bread to form ginger-bread, and in all these ways they prove very useful laxatives. Vegetable jellies taken with bread are less efficient, but vegetable jams are very useful, because in them we find a mechanical stimulus is given by the seeds or by the skins which the jams contain. A very favourite addition to the breakfast table is marmalade, which contains vegetable salts, sugar, and also the hard skin of the orange cut up into small pieces, which are rather indigestible and give a mechanical stimulus to the bowel.

Water, insufficient in *quantity*, or abnormal in quality, is also a cause of constipation. We find that civilised people are very often in the habit as it were of cheating the natural desire for water by taking wine, and many people, especially ladies, are in the habit of taking less water than they like because if they drink more water it will pass through the kidneys and the exigencies of society may prevent them from emptying the bladder as frequently as they would wish, and, therefore, they get into the habit of taking much less water than is advisable. A dryness of the bowel constantly results from this, the fæces become dryer and harder, and so constipation occurs. This constipation may frequently be lessened by simply allowing the patient to drink a large tumblerful of hot water or even of cold water, according to

[10] Lettsomian Lectures, 1886.
[11] Loc. cit., p. 124.

the season of the year, on rising in the morning, and sometimes a similar tumblerful of water taken just before going to bed aids the action of the bowels.

A wrong *quality* of the water is a frequent cause of constipation, and people living on a chalky soil and drinking hard water are very apt to suffer from this trouble. Where this is the case the patient should drink some of the ordinary bottled waters, such as soda water, potash water, or aerated waters generally. Not only should they drink this, but they should have their tea made with these waters instead of with the ordinary chalky water, as the quantity of lime in the water taken as tea is sufficient in some people, if the water be very chalky, to keep up the constipation, which will be relieved if the water taken in the form of tea be free from lime. It is very difficult for patients supplied with hard water to get their food cooked with water free from lime, and the only thing one can do is to advise them if possible to secure soft water for cooking purposes, for they will not use bottled waters on account of the expense.

Another very important point in the cure of constipation is habit, and this habit is also of great importance in regard to the production of constipation. The bowels usually tend to act once in twenty-four hours and generally nearly at the same time in the day. If a person who is accustomed to evacuate the bowels regularly omits to do so in consequence of having to hurry away somewhere or having some engagement which prevents him from going to the closet at the accustomed hour he is apt to break the habit, and it is sometimes much more easy to lose the habit than to regain it. It is very essential that the patient should go to the closet as nearly as possible at the very minute by the clock, and he should, if possible, go after breakfast; for, as Cash has shown, the introduction of food into the stomach, especially after the long fast during the night, tends to cause a peristaltic movement of the intestines, which brings some of the fæcal matter from the sigmoid flexure down into the rectum and tends to cause an evacuation. However, this regular time is in some cases impracticable in the morning on account of the calls of business which make the man leave his house quickly to catch a train to the city, or from other reasons. In such cases the bowels should be evacuated at bedtime or at some hour of the day when regularity can be secured. In cases where the patient suffers from hæmorrhoids or a tendency to prolapse it is much better that the evening should be selected so that the bowels shall be evacuated just before going to bed, because in persons suffering from hæmorrhoids or a tendency to prolapse there is apt to be a feeling of great discomfort consecutive to the movement of the bowels, and if the movement occurs in the morning they suffer from this discomfort the whole of the day. If the bowels are emptied just before retiring to bed they can wash the parts, return the hæmorrhoids or bowel, then go to bed, lie quiet and comfortable, and in the morning all trace of discomfort has passed away.

Exercise has a good deal to do with the movements of the bowels. Deficiency of exercise tends to cause constipation, partly, I believe, because the bowels do not get a mechanical stimulus applied to them by the contraction of the abdominal muscles. So that, as a rule, we advise our patients to take exercise; but a great many people will not take exercise, and I think a number of people cannot do so. In such cases we may supply its place by the use of massage, and massage to the abdomen certainly will counteract the tendency to constipation. In many persons the advantage of massage over ordinary exercise is that in massage the stimulus is applied not merely to the abdominal muscles themselves but really also to the bowels below, and it may be applied in various ways. There is first of all the massage which the patient himself may use. In sitting at stool and trying to elicit an evacuation he may simply with the ball of the left thumb press downward along the course of the descending colon and sigmoid flexure, pressing pretty deeply in when he comes nearly to the pubic arch. This action is useful even during the evacuation. Another action the patient may practise himself is rubbing the bowel gently onwards in the direction of the hands of a watch, and sometimes it is of advantage to use the fingers with a rotatory motion from the right iliac fossa upwards along the course of the ascending colon, across the transverse and then down the descending colon and sigmoid flexure.

There is one class of patients in whom I think exercise is disadvantageous. You will frequently find delicate women, especially those who have got some sort ovarian or uterine irritation, who tell you that the more exercise, particularly walking exercise they take, the more obstinate the constipation becomes, whereas when they lie quiet they are perfectly well. In such cases I believe there is a reflex inhibition of the peristaltic movements of the bowels from the irritated ovaries or uterus, and in some of these patients you may get an evacuation occurring from a remedy which is one of the last, possibly, you would think of employing—viz., opium. My attention was first directed to this by the case of a woman who was under the care of my friend, Dr. Litteljohn. The bowels were obstinate and my friend prescribed half a grain of opium so as to try to lessen the pain which she was suffering from an inflamed ovary. To his astonishment she got after the opium a natural evacuation, which she had not had for a long time before. Following on this I made a somewhat extensive trial amongst my out-patients at St. Bartholomew's Hospital, but the results I got were very uncertain. In some cases it acted, but in others there was no action at all. It is quite possible—indeed, it is probable—that some of the cases were unsuitable for it. In one private case I did not know exactly what dose to give, and I prescribed one minim of the tincture of opium every night. A week afterwards I had a report from the patient's husband to say his wife was no better. I replied "double the quantity." In a few days the report came, "she is rather worse." I then wrote to say "give her half the first dose." Three or four days afterwards I had a letter to say that the last medicine acted well, if anything a little too violently. I have never been able to make up my mind as to whether this result was due to suggestion, like the aperient action of a bread pill, or was actually due to the action of the drug. I am inclined to think it was actually due to the drug because the suggestion had been clearly applied to her mind by the one minim and the two minims and these did no good first of all and later did harm, while the half-minim dose caused an active evacuation of the bowels. At first it seems an absurdity to ascribe this action to the opium, but when one comes to think of the complex nature of the innervation of the intestine where there are at least two different systems of nerves—one which stops movement in the intestine and another which increases movement—one sees that it comes to be simply a question of a shifting of the action of a very delicate balance.

Another point that I wish to mention is the action of the floor of the pelvis in defæcation. In defæcation the contents of the intestine are passed onwards by its peristaltic movement, but this action is aided by the abdominal muscles which tend to press out the contents of the rectum in much the same way as they tend to press out the child in childbirth. But we all know that in childbirth the head of the child is driven not against the opening of the vulva, but behind it, so that the head of the child must be turned forward by the pressure of the perineum, frequently aided by the hand of the accoucheur. In the same way the muscles of the abdominal wall will press the fæcal mass backwards, not directly towards the anus, but behind it, in a line that would almost strike the tip of the coccyx, and if the finger be placed under the tip during the effort of straining this pressure is easily felt. Where the pelvic floor is very lax, as it is in women who have borne many children, you may find that the fæcal masses will accumulate in the rectum and form there a big accumulation, and the floor of the pelvis is so loose that it will not press them forwards so as to evacuate them through the anus. One great hindrance to complete evacuation of the rectum is the position adopted in this country during defæcation—i.e., sitting upon what is practically a chair with an opening in it. In nearly all other countries, and in all uncivilised places, where the bowels are moved in the open air, the position adopted is that of crouching with the knees somewhat apart. This position tends to cause a certain amount of stretching of the floor of the pelvis and to afford support to the fæcal mass as it is driven backwards by the action of the abdominal muscles. In cases where the patient must use the closet, a certain amount of tension is often imparted involuntarily to the pelvic floor by the patient leaning forwards at an acute angle. But this is not so good as the crouching position, and in patients who suffer from a lax condition of the pelvic floor it is advisable to tell them not to use the ordinary seat in the closet at all, but to keep a chamber-pot in the closet and sit over it in the normal crouching attitude. Sometimes great help is afforded by the patient putting the fingers just beside and a little in front

Digitized by Google

of the coccyx so as to support the pelvic floor and give a little pressure to the fæcal masses so that they may pass forwards through the anus in very much the same way as the accoucheur would support the head during parturition.

In some cases hydropathic treatment is very useful. The essentials of the hydropathic treatment are simply the application of wet compresses to the abdomen two or three times a day and sitz baths, cold in the summer and the chill taken off in winter. These must be followed or accompanied by exercise and drinking water, so that it is almost impossible to get the full effect of the therapeutic measures in a patient who is being treated at home.

Time would fail me to discuss the question of what medicines given by the mouth are best in constipation, of purgatives, of laxatives, of breakfast-pills, of dinner-pills, &c., and, moreover, they are most fully discussed in text-books and papers innumerable, and I shall, therefore, pass them over and proceed to discuss some points in regard to diarrhœa. I shall also pass over the ordinary

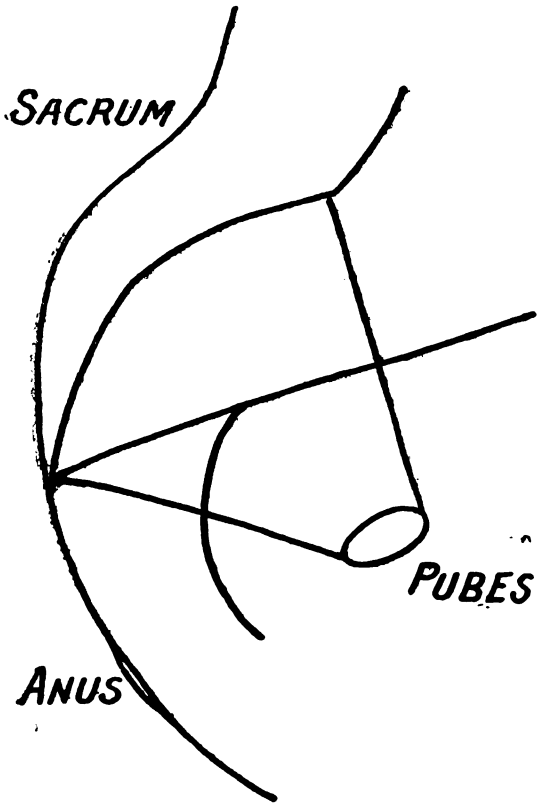

Diagram showing axis of pelvis and direction of pressure by abdominal muscles (after Cazeaux, Traité Théorique et Pratique des Accouchements.)

diarrhœa due to irritation of the intestine by the intestinal contents or by the decomposition of food, &c. I will simply draw attention to one method of stopping diarrhœa which is applied in various ways when the diarrhœa is due to decomposition of the intestinal contents by bacteria. The decomposition may be arrested and the diarrhœa stopped by simply starving the bacteria out. Thus where you find bacilli thriving upon certain diets you put the patient on an entirely different diet, and so get rid of the bacteria which have been living upon other foods. If a patient has been on a flesh diet and that has not succeeded, you put him on a farinaceous diet. Again, you may find that in certain children a farinaceous diet, or even a milk diet, is not successful, and you then put them on a meat diet, raw-meat juice, &c., and in this way starve out the bacteria which were causing decomposition of the milk or farinaceous food, so that when the ordinary food is again resumed the decomposing bacteria have been starved out and no decomposition will occur in the intestine.

I would also draw your attention to the excellent results which follow treatment by an entirely milk diet, particularly in patients coming from India and Afghanistan with chronic diarrhœa, and where every other method is utterly useless. As my friend Sir Joseph Fayrer has shown these cases must be treated just as one would treat a case of typhoid fever—viz., by milk, and nothing else whatever in the way of food. In some cases the patient even lays on flesh and is able to attend to his work, but this is not the general rule, as they usually have to be kept quiet in bed while they are on the milk diet.

I would next draw attention to an obstinate form of diarrhœa met with in connexion with irritability of the sigmoid flexure. It is a form of diarrhœa that is very often known as "morning diarrhœa." The patient has to get up very early in the morning, and perhaps has three to six movements before 11 A.M. After that he is pretty free, and probably after midday he has no action at all until next morning. This form of diarrhœa is sometimes not so severe, and occurs only in the shape of one movement just after breakfast, followed by one or two loose motions within the next hour or so, but both the severe form and the mild are by no means amenable to treatment. We give our patients opium, astringents, and sedatives such as bismuth, until we are tired, and yet by the simple means of regulating the diet results are obtained which cannot be got by ordinary remedies. The remedy is this: Tell them to take no liquid after five o'clock in the afternoon. It would seem that in such cases liquid taken after five or six o'clock tends to accumulate in the stomach or in the bowel, and it acts just in the same way as if the patient were to take a large dose of Carlsbad salts in the morning. In some of these cases dilatation of the stomach is present, but I do not think it is present in all. In all the cases I have met with I have got distinct improvement, and in many complete cure, by this simple regulation of taking no fluid after 5 P.M.

There is another form of diarrhœa the cause of which, I think, is often unobserved, and that is diarrhœa of a chronic irritating character; small motions but numerous and often accompanied with tenesmus, which is due to a prolapse of the sigmoid flexure into the rectum. As you know, the rectum is pretty firmly fixed to the bones of the pelvis, especially to the sacrum, so that although prolapse of the rectum through the anus is common in children, prolapse of the rectum is by no means very common in adults. But prolapse of the sigmoid flexure into the rectum is by no means uncommon in adults, and it sometimes gives rise to constipation, but frequently causes chronic diarrhœa. My attention was drawn to this very markedly in a patient whom I saw some years ago—a tea-planter who had come from Assam. He had suffered from chronic diarrhœa for from six months to a year before I saw him. The whole of his trouble dated from an attack of violent constipation which had lasted many days. To relieve this he took a strong purgative, and from the moment that this acted he had suffered from diarrhœa. All the remedies he had tried had failed. On examination by the bowel I found almost exactly the same condition as you would find in a child with a prolapsed rectum, only in this case the prolapse was as far up the rectum as one could reach with the finger. I found high up in the rectum regular bags of mucous membrane hanging down, and in the middle of these bags one could feel the opening into the sigmoid flexure. This man was treated chiefly by water enemata to keep the contents of the sigmoid flexure soft and by the application of catechu so as to exercise an astringent action upon the rectum. By carefully regulating the diet, so as to avoid hard irritating substances coming down from the sigmoid flexure, by keeping the fæcal masses in the sigmoid flexure quite soft so that there should be no mechanical pressure, and by injecting an astringent lotion (about two ounces of water to a drachm of tincture of catechu) into the bowel after each motion and retaining it as long as possible the patient was completely cured of the diarrhœa in a few months.

There is one other cause of diarrhœa to which I must draw attention and that is diarrhœa from malignant disease. The operation of examining the bowel is a disagreeable one both for the operator and for the patient, and for this reason it is frequently omitted. But in all cases of chronic diarrhœa I think it ought to be done. I have known several cases in which its omission has proved very disadvantageous to the patient. In one case which I have seen a woman had suffered from diarrhœa for two years. All that time she had been under constant treatment, but no examination of the bowel had been made, and I am sorry to say that

Digitized by Google

when I did examine the bowel I found malignant disease, which rendered colotomy necessary in about ten days. Another patient came to me for neuralgia of the perineum, and there again I found malignant disense of the rectum. Yet another patient came to me who said she was suffering from a little bilious attack and tendency to constipation. She looked so well, and all her friends said she was so well, that I did not at once make an examination; but later she told me she was passing a little mucus occasionally tinged with blood, and therefore I made an examination and found malignant disease of the rectum. Perhaps I would hardly have laid such stress upon this, but just before I came here to-day I saw a poor woman who had come to me in very much the same condition and not suspecting anything, but on examination I found there was malignant disease, and a colotomy was performed yesterday. In such cases colotomy is only capable of affording temporary relief. Whether, later, surgery will improve so far that the operation which has been done once or twice without much success will be successful one cannot say. I mean the operation of cutting a bit out of the bowel and sewing the two ends together. As a rule this has not been successful, but there is no reason why it should not be successful; and I think that if surgery advances in the next ten years as it has done during the last ten years in all probability it will be successful and that we shall save our patients' lives under circumstances where at present we are forced to say that the case is hopeless.

Stratford-place, W.

GLEANINGS FROM SURGICAL PRACTICE.

BY THOMAS BRYANT, M.CH., F.R.C.S. ENG. & IREL.,

CONSULTING SURGEON TO GUY'S HOSPITAL; PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND, ETC.

VII.[1]—OCCLUSION OF ARTERIES THE RESULT OF INJURY.

WHEN a surgeon is called to a case of injury to a limb—and for the moment I will assume it to be a lower extremity—over the upper part of which a heavily-weighted cart-wheel has passed, or to which some other crushing force has been applied, he naturally looks to its pulses, and if he finds they are all absent below the seat of injury he as naturally asks himself in what way an artery may be so damaged by a crushing force as to bring about its occlusion temporarily or permanently. If he happens to be well up in his subject he will know that an artery by a local contusing or stretching force may, in rare instances, become obstructed by hæmorrhage into its sheath, the effused blood mechanically so pressing the walls of the vessel together as to close its lumen, and that in military surgery this condition is fully recognised. In the Army Medical Museum, Washington, United States, Specimen 2114 demonstrates its truth. He will, however, also know that by far the most common consequence of a contusing or stretching force when applied to an artery is a more or less complete rupture of its internal or of its internal and middle coats; and when the external coat of the vessel is left intact—a common condition—these ruptured inner coats recurve and, forming an obstruction to the arterial flow, favour the formation of a blood-clot in the same way as in an artery completely divided by traction, or when divided and secured by torsion hæmorrhage is known to be prevented or arrested. If the inner coat or coats of a large artery are but partially torn the obstruction will not be complete and may be only temporary; if they are wholly torn and are healthy they will recurve in a valvular fashion; if they are wholly torn and diseased they will break up irregularly; but under both conditions they will form an obstruction to the flow of blood, help to bring about the formation of a blood-clot at the seat of injury, and so permanently to occlude the vessel, in the same way, as is now so well known, that torsion brings about the same results in a divided artery. If in the case before him the surgeon finds no evidence of a ruptured vessel or that the blood which has been effused is neither in quantity nor from its position competent to act as a compressing medium with sufficient power to cause arterial obstruction; if there are no displaced bones or fragments of bones which are capable of bringing this about, he must come to the conclusion that the serious condition he has to treat is one of obstructed artery from injury of its inner and middle coats as already described. Further thought will also tell him that the danger of the case is similar to that which has to be faced in all other examples of obstructed arteries from whatever cause, and that gangrene of the part which has been deprived of its arterial supply is the chief fear. If fracture or dislocation of a bone is found to complicate the case, its dangers are neither lessened nor altered in character, although the diagnosis of the true condition of the non-pulsating artery may not be clear. Indeed, when with a fracture or dislocation there is evidence, by the absence of pulsation in the main artery of a limb below the seat of fracture, that the arterial blood current is not passing, many questions at once arise, and the surgeon asks, Is it that the vessel is obstructed by partial rupture of its inner coats, as already alluded to, and that the outer coat is still intact? Is it that the artery is torn or divided with or without its associated veins? or is it that the vessels are simply pressed upon by effused blood, arterial or venous? or by displaced bone? When there is much effusion of blood into the tissues, and this effusion is deeply placed beneath a tense fascia, as in the leg, and no pulsation can be felt or bruit heard in the swelling to suggest arterial rupture, it is quite impossible to make out with any clearness the true condition of affairs or to which of the causes mentioned the obstruction may be due. Under these circumstances the treatment of the cases must be expectant, and on looking back upon past experience, and more particularly in the treatment of fractures of the leg, I can recall very many instances of this kind in which this difficulty was present and in which an expectant attitude gave a good result. Indeed, this was the case in by far the larger proportion of cases treated, and consequently the diagnosis of the exact condition of the vessels was not made out. Where the pulsation in the tibial vessels soon returned it is reasonable to believe that the vessels were in themselves intact and were occluded by outside pressure. Where the pulsation slowly returned after the lapse of many weeks the arteries had probably been organically injured and obstructed for a time. When pulsation failed to be restored it was probable that the vessels had been partially if not wholly ruptured and obstructed. Under all circumstances, however, an expectant attitude is the right one to assume in the treatment of these cases.

Before I pass on to illustrate this subject by the quotation of cases I must add that it should not be forgotten that the inner or middle coats of an artery may be so partially torn as not to be followed by the formation of a thrombus, or as a consequence obstruction to its lumen, but that as a result of the tear what is known as a dissecting aneurysm may form by the blood current finding its way between the ruptured coats and so separating them as to give rise to this rare variety of aneurysmal disease. In still rarer cases where obstruction is not complete the force of the blood may so dilate the external coat of the injured artery as to form a sacculated aneurysm.

CASE 3. *Laceration of the inner coat of the aorta, with fracture of the spine and laceration of the jejunum.*—An example of partial rupture of the aorta came under my observation in 1873 in a patient under the care of Mr. Durham. It was in a boy aged fourteen years who was admitted to hospital collapsed and dying with some abdominal injury which had been caused by the passage of a cart-wheel over his abdomen. He died a few hours after his admission. At the necropsy a complete separation of the first lumbar vertebra with its cartilage from the second vertebra was found to exist, and the cartilage had attached to it minute portions of spongy bone where torn from the second vertebra. The upper articular facets of the arch of the second lumbar vertebra were also broken off. The jejunum was found to have been separated from the duodenum and extravasation of fæces had taken place. There was some blood effused behind the peritoneum in front of the spinal fracture, and two slight lacerations of the liver on its anterior edge. At the level of the inferior mesenteric artery the inner surface of the aorta was torn transversely for half an inch across its inner coat. What the effect of this aortic laceration would have been is a problem which cannot now be solved. It may have led to the formation of a dissecting aneurysm in the way described or to the formation of a thrombus, and possibly the tear might have been repaired.

I will now pass on and illustrate this interesting subject

[1] Nos. I., II., III., IV., V., and VI. were published in THE LANCET of Nov. 2nd and 9th, Dec. 7th, 1895; Jan. 11th, Feb. 8th, and May 9th, 1896, respectively.

Digitized by Google

of the occlusion of arteries by the quotation of cases, and in so doing shall commence with examples drawn from injuries in the upper extremity; for I have before me the notes of four cases of obstructed brachial and one of obstructed axillary arteries. One was the consequence of a crush, but was not complicated with wound or fracture. Another was associated with displacement of the forearm and lower epiphysis of the humerus backwards. Two were complicated with fracture of the humerus, and one with a lacerated wound into the axilla. All five recovered. The first case I shall give will be one of occlusion of the brachial artery the result of a crush.

CASE 4. *Contusion of arm; occlusion of the brachial artery; recovery.*—A man aged thirty-two years was admitted into Guy's Hospital on June 25th, 1875, having had his arm crushed between the buffers of two railway trucks. On examination no bones were found to have been broken, but the whole limb was much swollen and ecchymosed from the hand to the axilla, clearly from effused blood, and there was neither pulsation nor arterial thrill in any of the arteries of the limb. The arm likewise was cold. The expectant treatment was adopted. The arm was wrapped in cotton wool, placed on a splint, and raised slightly. To it gentle pressure was applied by means of a bandage. The swelling gradually subsided. In three weeks pulsation returned in the radial artery; in six weeks the arm was comfortable, but no pulsation ever reappeared in the brachial artery. Whether the brachial artery was torn across or only obstructed in one of the ways previously described must be an open question. I am disposed to take the latter view, although in a case I shall next quote in which the axillary artery was clearly torn across an equally good result ensued.

CASE 5. *Lacerated and obstructed axillary artery in a boy aged eight years; good recovery.*—A boy aged eight years many years ago was brought into Guy's Hospital, under the care of the late Mr. Hilton, with a lacerated wound on the inner side of his arm extending into the axilla which had been caused by his falling from some height on to a spike of an iron railing. He was brought to Guy's Hospital in a collapsed condition with this gaping wound, which I had an opportunity of seeing soon after his admission. The axillary artery had evidently been torn across, for its two separated ends were visible, and the upper pulsated. There was no pulsation in any of the vessels of the arm below the seat of injury. The wound was treated as was then customary and the arm was kept warm with wool and slightly elevated. The artery was not touched. A steady repair ensued and the wound healed in five or six weeks; by that time a pulsation in the wrist was made out. In this case all bleeding was prevented by the laceration of the axillary artery, and I hold that the practice which was adopted was the right one, although every surgeon should before he adopts a like line of treatment satisfy himself that the lacerated end was secure. I have seen a case in which the superficial femoral artery was torn across in a like way associated with a severe fracture of the femur, which was likewise left to nature, and a good recovery ensued. It occurred in the practice of the late Mr. Bransby Cooper.

CASE 6. *Separation of the lower epiphysis of the humerus from the diaphysis and displacement of the epiphysis with the bones of the forearm backwards; occlusion of the brachial artery.*—A boy aged five years was admitted into Guy's Hospital on May 27th, 1878, under my care, having injured his elbow one week previously in falling down stairs. The limb was cold, swollen, and pulseless below the elbow. The forearm with the lower epiphysis of the humerus was displaced backwards, and the anterior edge of the extremity of the diaphysis was pressing seriously upon the brachial artery, which was in front. When the deformity was reduced pulsation did not return in the vessel. The limb was put into a good position and fastened in a splint after having been raised and well wrapped up in cotton-wool; everything went on well. Subsequently, on the seventeenth day after his admission, or the twenty-fourth day after the accident, pulsation returned in the radial artery, but when the child left the hospital in the sixth week no pulsation had returned in the brachial artery below the seat of injury. At that spot the vessel was clearly occluded.

CASE 7. *Compound fracture of the humerus, with occlusion of the brachial artery; good recovery.*—A woman aged forty-three years was run over on Oct. 31st, 1887, and subsequently admitted into Guy's Hospital under my care with a compound fracture of the humerus about its middle third and absence of pulsation in the brachial artery with its branches. The wound was a lacerated one, as the accident was brought about by the passage of a cart-wheel over the limb. The wound was well washed with iodine water, and dressed with iodoform gauze and mercuric wood wool tissue. The arm was put up in splints, which included the forearm, after having been well wrapped in cotton-wool, and a good recovery followed. Fourteen weeks after the accident a feeble pulsation returned in the radial artery, but the brachial vessel was permanently occluded.

CASE 8. *Compound fracture of the humerus into the elbow-joint, with occlusion of the brachial artery; excellent recovery.*—A lad aged sixteen years was admitted into Guy's Hospital under my care on May 29th, 1873, the wheel of a van having passed over his arm above the elbow. The humerus was broken above the condyles, and there were two lacerated wounds into the elbow-joint exposing the inner condyle of the humerus and olecranon process of the ulna. There was no pulsation in any of the arteries below the centre of the brachial. The wound, having been well cleaned, was sealed with lint soaked in the compound tincture of benzoin—as was at that time my general practice—and the arm was put up in splints with the forearm well covered with cotton-wool and slightly raised. Everything went on well and quick union of wounds and bone followed. Every movement of the joint was retained, but pulsation never returned in the brachial artery, although it did in the vessels of the forearm some months later. The inner and middle coats of the brachial artery had been clearly ruptured in this case by the contusing force.

These three cases may be read together, although in Case 6 the obstruction to the brachial artery was probably due to the injury it had sustained by the forward pressure of the lower end of the diaphysis of the humerus, and the other two by the same force which had produced the fracture. In all three it is to be noted that a good recovery took place, and when the cases were under care I was apt to point out that it was more than probable that their well-doing was much influenced by the fact that the amount of blood which supplied the injured parts was somewhat less than it would have been had the vessel been patent; at any rate, it may be stated that in the three cases there was no temperature worth recording and a steady convalescence.

Cases of occlusion of the arteries of the lower extremity will now occupy my attention and it need not be said that such are of a far more serious nature than are those of the upper on account of the arteries being larger. I have five examples before me which I shall briefly quote.

CASE 9. *Contusion and occlusion of the external iliac and common femoral arteries; recovery.*—A man aged twenty-six years was admitted into Guy's Hospital on June 29th, 1875, with severe bruising of his abdomen from the umbilicus downwards to below Poupart's ligament and absence of pulsation in the right femoral and external iliac vessels, with coldness and numbness of the left foot, also with pain in the lumbar region. He had passed his urine without difficulty. It seemed that the day before his admission he had fallen off a pleasure van, and that the two side wheels of the van had passed over the lower part of the abdomen when he was lying on his back. He was treated by slight elevation of the injured limb, which was wrapped in cotton wool and placed in a splint. On the fourth day warmth had returned to the foot and feeble pulsation was felt in the anterior tibial artery. On the seventh day the whole limb was warm, and in five or six weeks the limb was natural, although the pulsation in the tibial arteries was not so strong as it was in the normal leg, and there was no pulsation in the external iliac or common femoral vessels.

CASE 10. *Ruptured popliteal artery; occluded artery.*—A man aged thirty-two years applied to Guy's Hospital on Aug. 5th, 1862, with extreme distension of his left leg up to the popliteal space and much pain. The swelling had come on rapidly when he was at work after a sudden pain and sound of a snap in his knee. He was admitted under the care of Mr. Birkett when I was his assistant. No pulsation was to be felt or heard in the arteries of the leg, but in the swelling the man felt pulsation like that of a clock. The limb was fixed on a splint, wrapped in cotton-wool, and slightly raised. In a few days the swelling began to subside and pain to diminish. On the fourteenth day the sensation of pulsation ceased and the swelling steadily diminished. At the end of three weeks the articular arteries about the knee were clearly enlarging and convalescence was soon re-established. Four months after leaving the hospital he reappeared with a deep abscess in the posterior and lower part of the left thigh.

Digitized by Google

When this was opened much broken-down blood escaped with pus; a good recovery followed. There was, however, no pulsation to be felt in the bloodvessels. The abscess was doubtless due to the breaking down of blood which had been effused at the time of the original accident and had not been reabsorbed.

CASE 11. *Fractured pelvis with obstruction of the external or common iliac artery; recovery.*—A man aged fifty-three years came under my care in 1873 after a severe hunting accident he had sustained two weeks previously in a fall from his horse with his horse on him. After the accident he passed much blood from the urethra and had to be relieved by the passage of a catheter. Any movement of the pelvis caused great pain, and this pain passed down his right leg, which was cold and numb. The scrotum was much swollen with the whole of the right groin and the lower part of his abdomen. When I saw him two weeks after the accident blood was still flowing from the urethra, but not from the bladder, and the passage of a catheter was easy. The right lower extremity was cold, pulseless, and swollen. The scrotum was much ecchymosed and the right ilium was evidently fractured from the anterior third of its crest downwards through the brim of the pelvis. No pulsation could be felt in the right external iliac artery as high as could be reached. A catheter was passed and fixed in; a bandage was secured round the pelvis after some strapping had been applied to fix the broken bone, and the right lower extremity was wrapped in cotton wool after it had been rubbed with the hand upwards when slightly elevated. It was then laid upon a splint with its lower end raised. Everything subsequently went on well. All urethral hæmorrhage ceased and swelling of the parts subsided. In six weeks the tibial vessels were felt pulsating and in another three the superficial femoral artery was evidently open. After convalescence was established no pulsation was ever detected in the external iliac or common femoral artery. In 1890, seventeen years after the accident, when the patient was seventy years of age, he married and was in excellent health. He would not admit that his right leg was colder than the left.

CASE 12. *Fracture of the pelvis; occlusion of the external iliac artery; gangrene of the foot and leg; amputation; death.*—A man aged twenty-one years was admitted into Guy's Hospital under my care on Feb. 15th, 1892, after having been knocked down by a piece of falling timber striking him on the right hip. When seen his hip and whole right lower extremity was much bruised, the discolouration including the right side of his pelvis and right iliac fossa. The ilium was fractured through the right pubic portion and the right iliac artery was evidently obstructed from the absence of all arterial pulsation in the vessels of the limb. In spite of careful treatment gangrene ensued and on March 14th, one month after his admission, amputation at the knee-joint was performed. The man, however, died on the 25th, eleven days later, from septicæmia. After death it was found that fracture of the pelvis had extended into the hip-joint. The external iliac artery at a point corresponding to the fracture of the brim of the pelvis was obstructed, the internal and middle coats of the vessel having been ruptured by some over-extension of the artery by the broken bone. The external coat was intact; within the artery, besides the recurved inner coats, there was a firm blood-clot above and below the injured part.

CASE 13.—*Fractured pelvis through the thyroid foramen; occlusion of the iliac artery; rupture of the urethra and partial rupture of the bladder.*—A youth aged twenty years was admitted into Guy's Hospital on July 17th, 1876, under the care of Mr. Forster, after having been crushed between the buffers of two railway carriages. When admitted there was an elastic, non-pulsatile swelling above the right Poupart's ligament, an absence of pulsation in the right femoral artery and its branches, a cold right foot, and a scalding pain down the right knee and leg. There was a wound close to the rectum through which a finger could be passed up to the symphysis and there was a large blood-clot in the rectum, but no wound could be felt in it. No fracture was then made out. The urethra was clearly ruptured and as a catheter could not be passed through the penis the perineum was laid open and the bladder emptied, its contents being like coffee grounds. The patient died thirty-six hours after the accident. At the post-mortem examination a fracture was found to have passed through the right pectineal eminence into the thyroid foramen, and a second through the ramus of the ischium. The symphysis pubis was separated and the coccyx transversely fractured. The urethra was torn across and the peritoneal coat of the bladder ruptured. The right external iliac artery for two inches was much bruised, and in slitting it up a clot was found in its interior. The two inner coats of the vessel had been ruptured and were curled up occluding the vessel. The external coat was intact.

In the last three cases it may reasonably be assumed that the external iliac artery was in each obstructed by the overstretching of its coats upon a broken fragment of the pelvic bones. Indeed, in all cases of fracture of the pelvis the fear of this complication should ever be in the mind of the surgeon who has charge of the case; in Case 11 this fact was at first overlooked, and it was only when the effects of the injury showed themselves that I was consulted. Happily the case did well.

THE TREATMENT OF OCCLUDED ARTERIES.

That the ultimate consequences of an obstruction to a large artery of an extremity will greatly depend upon its treatment is a truism to which every surgeon should be alive, for it should be fully recognised that any want of appreciation of the requirements of a case of this nature is sure to be followed by injurious if not fatal consequences, whereas with due care good results may often be secured to both limb and life. A limb when suddenly deprived of its arterial blood-supply is more liable to become the subject of gangrene than when the process has been of a more gradual nature; primarily, from the sudden deprivation of its tissues of their natural nutriment—the blood: and secondarily from the blood stasis which invariably follows the accident, either as a consequence of the simultaneous injury to the accompanying veins of the injured artery or from the loss of the *vis a tergo* normally supplied by the heart through its arterial system, as well as of all the other forces which favour the venous flow,—the malposition of the affected limb after the accident, and particularly its dependent position, with want of care in other ways in its treatment, having a powerful influence on the result. The object of the surgeon in the treatment of any case of this kind is consequently to encourage in all ways the arterial as well as the venous circulation of the limb, and particularly to guard against anything like blood-stasis in the tissues. With these views he must place the limb—say the lower extremity—upon a splint to keep it quiet, after it has been carefully rubbed upwards and gently kneaded to encourage the flow of venous blood through the muscles and deeper parts, and care must be observed that this splint with the limb upon it is raised sufficiently, but not more than sufficiently, to help the return of venous blood to the heart, but not enough to interfere with the supply of arterial blood through the new arterial channels which have to be enlarged to compensate for the obstruction of the main vessel. The foot should consequently be not raised more than one or two inches higher than the knee, and the knee than the hip. To do more would militate much against the arterial supply becoming sufficient for the nourishment of the limb, and to do less would encourage blood-stasis. The limb from being deprived of its warm arterial blood-supply being cold requires warmth, but if this be supplied suddenly or at a too high degree more harm than good will follow its application, for by excess of warmth blood will be drawn to the part when the power of the tissues to pass it on is lost or almost lost, and the blood-stasis, which is so much to be dreaded, is thereby encouraged. The warmth should consequently be applied to the limb cautiously and not till the venous circulation of the limb has been helped by gentle rubbing upwards and kneading the deeper tissues with the warm hand, below the seat of injury. Subsequently the limb should be swathed in cotton-wool, several layers being used, and the whole be bound together with a flannel bandage, gentle pressure being applied by means of the bandage.

The general treatment of the case should be based upon the same requirements; everything like over stimulating should be avoided and simple nutritious food given. Wine and spirits must be administered with great caution. Should gangrene follow in spite of right treatment, amputation will be called for, but such a measure should not be hastily undertaken; indeed, it should not be performed until some indication is afforded to the surgeon of the extent to which the gangrene is likely to spread; until, in fact, some kind of line of demarcation can be made out, and then the amputation should be undertaken well above this line in healthy tissues.

Digitized by Google

In a case of this kind amputation need not, however, be performed so far from the line of demarcation as it is expedient to act in cases of senile gangrene, for in this latter affection the vessels of the limb are known to be diseased, whereas in those now under consideration the vessels in all probability are sound except at the seat of injury. If septic changes take place in the limb surgical interference may be hastened; but if the limb has been rightly treated and well raised it will probably wither up and become dry, whereas if the limb has become swollen and œdematous from blood stasis, from whatever cause, septic changes are sure to show themselves. Under the former circumstances, where the gangrene is of a dry form, delay is to be sanctioned; under the latter, where it is of the moist form, surgical interference will not only be called for at an early period, but have to be carried out under the most unfavourable conditions.

In the treatment of cases of fracture, simple or compound, complicated with obstructed arteries, an expectant attitude should, as a general rule, be observed, for in the majority of cases of this kind the limb is sufficiently well nourished to undergo repair and for good union of the bones to take place. It is in exceptional cases alone that gangrene follows and amputation is called for. Before I conclude this article I propose to quote the brief notes of seven cases, in each of which at some antecedent period a large artery had been obstructed by surgical methods and recovery had followed. The cases came before me for some independent surgical operation and speak for themselves. It is to be regretted that the reports are not as complete as could be wished, but they are worth recording even as they are.

CASE 14. *Ligature of the common carotid artery three years before.*—In 1863 a man came before me with a thecal abscess. He was in good health and had been so since Jan. 3rd, 1860, when the late Mr. le Gros Clarke had ligatured his common carotid artery for a wound into it, the result of a stab, at St. Thomas's Hospital.

CASE 15. *Ligature of the common carotid artery twenty years previously.*—In 1881 a man aged forty-one years was admitted into Guy's Hospital under the care of Dr. Wilks for tetanus, from which he died. Twenty years before—that is, in 1861—he was in the same hospital under Dr. Wilks for a sloughing throat, which was complicated with such arterial hæmorrhage as to call for the application of a ligature to the left common carotid artery by the late Mr. Cooper Forster. He rapidly recovered after the operation and had worked at his trade in good health ever since. At the post-mortem examination made by Dr. C. H. Fagge the left carotid was found to be small but easily dissected out, and retained the appearance of the artery externally. It was occluded by a firmish, delicate coagulum, which blocked the channel from the bifurcation into external and internal to one-third of an inch from its origin at the aorta. Its lower end was channeled for a line or so by a canal which showed when the lower end was inspected a central depression, but it did not go anywhere, although by its appearance it was expected that there had been a restoration of the canal (canalisation). The clot was of a delicate nature, and when the artery was opened and the clot separated from it there was very little coagulum left, a thin end of brownish colour and somewhat delicate consistency remained, which was more like connective tissue than clot. It was worthy of note, too, that the artery-wall looked quite healthy when the clot had been removed from it. It was thrown into longitudinal folds from contraction upon the contents, which insufficiently distended it. The coats still possessed, apparently, the yellow, tough consistency of arterial coat. The internal carotid was blocked in a similar manner to the common carotid, but the plugging was less complete, and Dr. Fagge was disposed to think that there had been some restoration of its circulation through the external carotid. At all events the common carotid had a small free passage into the internal carotid at the bifurcation, and the clot in the internal carotid was of such tenuity that he could not say the artery was quite blocked. A delicate coagulum extended as far as the base of the skull. The internal jugular vein seemed to be very small, not so large as the normal external jugular.

CASE 16.—*Fracture of the thigh in a man who had not completely recovered from a hemiplegic attack six years previously and had had his subclavian artery ligatured twenty-nine years previously for aneurysm.*—In 1855 a man aged sixty-four years was admitted into Guy's Hospital under the care of Mr. Birkett with a fracture of his right femur, which united well. Twenty-nine years previously he had had his subclavian artery tied for axillary aneurysm at St. Thomas's Hospital and was in good health subsequently up to six years before his admission into Guy's Hospital, when he had a fit and became hemiplegic on the right side—the side of the fracture—from which he never completely recovered.

CASE 17. *Death from rupture of an abdominal aneurysm in a man who about six years previously had been cured of a popliteal aneurysm by pressure.*—A man aged thirty-four years came under my care in December, 1880, with an abdominal aneurysm and also a popliteal aneurysm in his right lower extremity. He died suddenly soon after his admission from a rupture of the abdominal tumour. He had been under my care about six years previously for a popliteal aneurysm in his left leg and was cured by means of digital and instrumental pressure. He had been working at his trade up to a few days of his death. At the post-mortem examination much blood was found in the peritoneal cavity, and from the anterior wall of the abdominal aorta, between the renal arteries and involving the mouth of the cœliac axis and the superior mesenteric artery, there was an oval aperture leading into a thin-walled sac which was about the size of an orange; in its upper part this had ruptured. The specimen of the artery was removed for subsequent examination by the then registrar, Mr. Symonds.

CASE 18. *Thoracic aneurysm following the cure of a popliteal aneurysm two years previously by pressure.*—A man aged thirty-five years was admitted in 1881 into Guy's Hospital with an aortic aneurysm from which he died. In 1879—two years before—he had been treated by Mr. Durham for a popliteal aneurysm which was cured by pressure. The preparation, like the last, was taken away to be carefully examined, but the report has not yet, unfortunately, been completed.

CASE 19. *Case of cured aneurysm of a popliteal artery in a man who died nine months later from an aortic aneurysm.*—A man aged forty-three years was admitted in 1869 in a dying condition into Guy's Hospital from an aortic thoracic aneurysm. He had been in the London Hospital in July, 1868, and was there cured of a popliteal aneurysm by pressure. The necropsy was made by the late Dr. Moxon, and he reported that "the femoral artery at the seat of compression was quite healthy." The sac of the old aneurysm was the size of a small walnut and filled with a firmish clot of a reddish-brown colour, easily separable from the sac. The orifice into the sac was not made out, as it was in the line of section of the aneurysm.

CASE 20. *A man aged forty-seven years who nineteen and seventeen years previously had had his femoral arteries ligatured for popliteal aneurysms and had worked ever since as an orange porter.*—A man aged forty-seven years came to Guy's Hospital in December, 1860, for a sprained knee. In 1841, when he was twenty-eight years of age, or nineteen years before this note was taken, Mr. Bransby Cooper applied a ligature to his left femoral artery for popliteal aneurysm and two years later to the right femoral for the like affection. He rapidly recovered after both operations, and returned to his work as an orange porter, which he had followed up to the time of his accident.

THE SURGERY OF EMPYEMA,

WITH DESCRIPTION OF A NEW SELF-RETAINING EMPYEMA TUBE.[1]

BY CORNELIUS A. GRIFFITHS, F.R.C.S. ENG.

I SUPPOSE I may take it for granted that everyone will agree with my saying that when a patient presents the physical signs of fluid in the chest it is the imperative duty of the practitioner in attendance in the first place to find out the nature of that fluid and then to adopt measures for its removal, the particular means used being determined according to the amount and nature of the fluid present. The general physical signs of pleural effusion I need say nothing about. Concerning the differential diagnosis between serous and purulent effusion various statements have been

[1] Abstract of a paper read before the Cardiff Medical Society on Feb. 7th, 1896.

Digitized by Google

made with reference to the conduction of breath-sounds through the fluids. In cases of empyema which I have examined I have found that this auscultatory sign is by no means constant. In some cases I have found the breath-sounds well conducted, giving high-pitched tubular breathing, while in others there has been no conduction at all or a condition intermediate, in which faint distant breath-sounds have been heard; so that from my own experience I attach very little importance to the stethoscope in the differential diagnosis of pleural effusions.

As a practical surgeon I am content to leave these diagnostic niceties and resort at once to the simple and only absolutely reliable method of clearing up the diagnosis—by removing a sample of the fluid for examination by means of an exploring needle. For this purpose one should use a needle similar to, but longer and larger in the bore than, the ordinary hypodermic injection needle. I once, several years ago, used an ordinary hypodermic needle for this purpose and have never forgotten the lesson it taught me. I was acting as locum tenens for a friend and I had a young patient with the physical signs of fluid in the chest. I proceeded to explore the chest in order to confirm my diagnosis and see the nature of the fluid. The only available needle for the purpose was an ordinary hypodermic syringe. I failed to get away any of the fluid and was naturally disappointed; but a few days afterwards the child was operated upon and relieved of a good quantity of purulent fluid from the chest. To use the same needle and syringe one time for exploration and another for hypodermic injection is an unjustifiable practice which I think cannot be too strongly condemned. It is unfair to one's patients to give them injections from a syringe which may have recently had foul pus in it, no matter how much one may have tried to clean it, and it is bad surgery to use the small needle.

In order to save carrying about more than one syringe I have adopted a plan which is at once simple and satisfactory. In my pocket hypodermic case I carry a large (exploring) needle which can be attached to the hypodermic syringe, but for purposes of exploration I intervene between needle and syringe a small piece of glass tubing, attached at either end by means of a little rubber tubing to the needle and syringe. The nature of the fluid can be seen when it reaches the glass tube, so none need reach the barrel of the syringe. The whole thing goes into my waistcoat pocket. If fluid is not found at the first puncture the needle point should not be wobbled about in the chest; the depth may be varied, as the pleura may be thickened, or the needle should be withdrawn and reinserted in another place.

The diagnosis of empyema being completed the question of surgical treatment should be at once considered. No good can possibly come of delay, and although we do occasionally meet with patients who have recovered after discharging an empyema through the lung they should be regarded as cases recovered in spite of neglect rather than indications favouring an expectant treatment of empyema. Delay also favours compression, perhaps hopeless collapse of lung, which, by reason of its structure and anatomical relations, is bound to give way and shrink before an increasing collection of pus. A neglected empyema, if it does not discharge through the lung and air passages, may point between the ribs or escape through or by the side of the diaphragm. The front of the chest at the fourth or fifth interspace is said to be the favourite place for an empyema to point. I have seen that part selected, but have also operated on one pointing just below the angle of the scapula. Various other situations are met with, and one case of an empyema discharging at the umbilicus is recorded.

The choice of operation for the relief of empyema lies among the following: (1) aspiration; (2) syphonage; (3) simple incision with insertion of a drainage-tube, and with or without counter incision; and (4) incision with resection of a portion of one or two ribs and drainage. I have had no experience of the first two methods—namely, aspiration and syphonage. I know they have many advocates, but I prefer treating a collection of pus in the pleural cavity on the same general principles that are applied to similar collections in other parts of the body—viz., giving free exit at once to the pus that is present and providing free drainage for what may follow.

A great deal has been said concerning the best place for making the incision; here, again, I prefer following the general surgical rule and make my incision in the most dependent position; and taking into consideration the somewhat barrel-shaped outline of the chest [illegible] the fact that patients generally prefer to lie upon the ba (not upon the affected side as much as is stated), I usual select the eighth or ninth interspace just outside the line the angle of the scapula. Localised empyemata must course be treated upon their own grounds.

Shall we or shall we not resect a portion of rib? is a questi which has given rise to a great deal of controversy. I thin the advantages gained by resection are quite sufficient justify the proceeding. The chest cavity can be explore masses of lymph removed, and better drainage secure I have often seen great difficulty experienced with t drainage-tube after the operation of simple incision wh the tube has been pushed out, as is so frequently the cas or has been withdrawn for cleansing or some other reas The ribs which have fallen together after evacuation of t pus—or the valvular nature of the opening, or, perhap both—afford an obstacle to the reintroduction of t tube, which causes a great amount of unnecessa suffering to the patient and annoyance to the su geon. This is easily avoided by removal of an inc of rib. One of the recent cases upon which I ha operated with resection has helped to convince me of t superiority of this operation over that of simple incisio After removing some rib in the usual sub-periosteal meth and then opening the pleura I introduced my finger an felt a quantity of loose semi-solid matter in the cavity with a pair of forceps, guided by my finger in the chest removed quite a double handful of this coagulated lymp I cannot help thinking that if I had simply incised and p in a tube I should have had considerable trouble by blockag of the tube, and that the patient would have made only tedious recovery. As it was the temperature fell to norma the evening of operation and the patient was about with t wound healed early in the second week. I do not thin much weight attaches to the objections raised again resection; the time need be very little prolonged beyon that occupied in simple incision, and the loss of an inch rib will not be seriously felt. The increased risk of pyæm infection through the cut ends of the rib is, I think imaginary rather than real. Adhesions that may be felt the chest should not be interfered with; their rupture migh be attended by hæmorrhage and perhaps serious injury lung substance, and their presence may help to preve collapse of the lung. I am not in the habit of irrigatin the cavity unless the pus is very flaky; no fluid should forced into the chest. Counter-openings are not necessar and loculated empyemata are better treated by separa incisions rather than by breaking down dividing partitions.

Hitherto I have used for drainage a rubber tube wi a mackintosh guard. I now venture to introduce a ne pattern which Messrs. Down Brothers have made for m from a model which I sent them. The tube is a metal co it has a shield at its outer extremit and at its inner end there are a coup of retaining flanges which are to b opened out when the tube is in sit This is done by simply turning th handles seen upon the face of th shield. These serve the double pu pose of handles and indicators of th position of the flanges, as they pos in the same direction, one flange an one handle being attached to the en of a revolving rod or axle running th length of the tube. The flanges ma be turned through one or two rig angles, as may be desired. No har can happen to the lung by openin and closing the flanges, as they easi revolve between the parallel viscer and parietal pleural surfaces, and the shield is protecte against the tube being driven inwards. The invention wi I hope, prove a useful one. I am indebted to Messrs. Dow Brothers for carefully carrying out my instructions a turning out a neat, well-finished instrument.

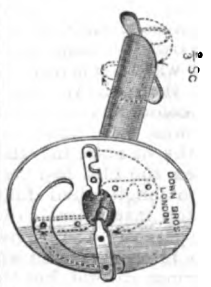

FIG. 1.—Self-retaining Empyema Tube (open).

Cardiff.

SUPERANNUATION GRANT.—Mr. Albert B. Dy M.R.C.S. Eng., has been awarded by the Brentford Board Guardians a superannuation allowance of £128, based upo his salary, supplemented by an additional annuity of £5 on his resigning the medical officership to the Workhouse Infirmary.

HE FLUID CONTAINED IN OVARIAN CYSTS AS A MEDIUM FOR THE CULTIVATION OF THE GONOCOCCUS AND OTHER MICRO-ORGANISMS.

BY FREDERICK J. McCANN, M.B., C.M. EDIN., M.R.C.P. LOND.,
YSICIAN TO OUT-PATIENTS AT THE SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.

Two years ago it occurred to me that some use might be ade of the fluid contained in ovarian cysts as a medium for e cultivation of micro-organisms. I was specially anxious devise a ready method for the cultivation of the gono-ccus, as the difficulty of growing this organism outside e human body has deterred the usefulness of Neisser's dis-very as a clinical test. After repeated trials I succeeded obtaining a medium of good transparency on which the nococcus was successfully cultivated.

Method of obtaining the fluid.—It is necessary to obtain ecimens of fluids which are fairly clear; at the same time ntamination with blood should not prevent the fluid being ed. Modern antiseptic precautions during abdominal erations render the collecting of the fluid less difficult. ie trocar used to tap the cyst should be sterilised by iling. The first portion of the ovarian fluid being rejected e remainder is collected in tall cylindrical glass jars, known bacteriologists as "blood jars." These glass jars, which e provided with an accurately fitting glass stopper, are st cleansed with a 1 per cent. solution of mercuric chloride llowed by absolute alcohol. The stopper should be smeared th vaseline containing corrosive sublimate to prevent it coming fixed and to exclude atmospheric dust from the r and its contents. The fluid collected in the jars should allowed to stand for twenty-four hours in a cool place—g., an ice safe—when any sediment will have been de-sited at the bottom. It will be well to boil a portion of e fluid in a test-tube in order to determine the proportion of bumin. If the fluid turns solid on boiling it will prove a od medium. As the proportion of albumin in cystic con-nts varies considerably it is specially needful to adopt this ecaution.

Method of preparing the medium—The fluid having been oled as described the supernatant portion is removed by eans of a sterilised pipette and transferred to sterilised test-bes provided with a sterilised cotton-wool stopper. The test-bes are then placed in a slanting position in an incubator, nich should be kept at a temperature of from 66° to 68° C. r four hours. After four hours the fluid is of gelatinous nsistence and good transparency. This method is prefer-le to that of running the temperature up gradually until lidification occurs, as the latter requires very careful tching and the risk of destroying the transparency of the edium is greater. If careful precautions be taken when e fluid is collected preliminary sterilisation will not be cessary. It is well, however, to test the sterility of the edium before use by keeping the tubes in an incubator at °C.

Method of cultivating the gonococcus.—It will be found that e gonococcus grows better when little mounds of pus are aced on the medium instead of streaks or punctures. The oculated test-tubes should be placed in a glass vessel half led with distilled water and provided with a well-fitting ass plate. The object of the distilled water is to moisten e air in the vessel so that the surface of the medium is pt in a similar condition. The glass vessel containing the st-tubes should be placed in an incubator kept at from 30° 34° C. The cultures thus obtained, after twenty-four to nty-eight hours, are very thin, scarcely visible, greyish-llow by reflected light, the surface smooth and moist, the ges diffusing into the surrounding medium which is not uefied. Re-inoculations can be made and the cultures opagated through several generations. The essential fficulty in the cultivation of the gonococcus exists in the pid overgrowth of this organism by other pus organisms. ould such an overgrowth occur the gonococcus may be parated by successive re-inoculations until a pure culture is tained.

Microscopic examination of the culture.—For this purpose a rtion of the culture is removed on the point of a sterilised atinum needle and transferred to the surface of a cover ass, another cover glass is superimposed, and the two pidly separated. After drying the cover glasses may be stained with fuchsin as described in a paper by the author published in the West London Medical Journal.[1] Examination under the microscope shows that gonococci only are present, which can be verified by the use of Gram's method.[2]

The utility of this medium.—In addition plate cultures can be made. To economise the amount of fluid used a mixture with agar agar may be employed as with blood serum. Further experience will show whether the medium prepared as described will prove equally efficacious for the cultivation of other micro-organisms.

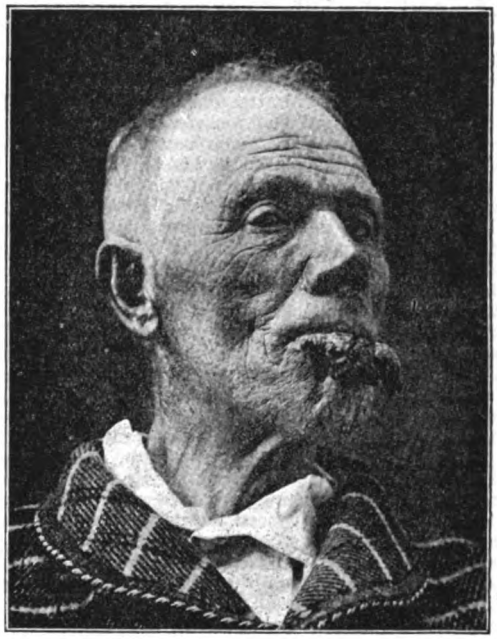
Curzon-street, Mayfair, W.

A CASE OF WART HORN OF THE LIP.

BY H. A. LEDIARD, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO THE CUMBERLAND INFIRMARY.

GROWTHS known as wart horns are rather matters of curiosity than of special pathological interest, as there is probably not much more to be said of their history or clinical features. The face and head are the commonest sites in which they are found, but I remember having seen one of small size on the shin of an elderly person, and when visiting Mr. Hutchinson's museum in 1894 I saw a recent specimen of an immense wart horn which had been removed from the leg. On referring to Dr. Crocker's Treatise on Diseases of the Skin under the heading of Cornu Cutaneum (p. 361) it is stated that the analysis of some collected cases shows that nearly half the horns occur on the hairy scalp, forehead, or temples, about one-fifth on the rest of the face and especially the nose. No mention is made of the origin of a horn from the lip, and the case I am recording may possibly be of some rarity and worthy of a brief notice. The photograph was taken by Dr. Eves, house surgeon, and from his notes I extracted the following particulars.

A platelayer aged sixty-nine years was admitted into the Cumberland Infirmary on July 24th, 1895. The patient, a



healthy old man, had had a growth on the lower lip for four years. It had caused no pain and commenced as a wart and grew gradually. At times pieces fell off, but there had never been any bleeding. Considerable annoyance, however, was created on account of the offensive smell given off. From the illustration the whole of the lower lip will be seen to be occupied by a large warty excrescence, which at one corner has developed into a large wart horn of considerable bulk. The lip was somewhat everted from the weight of the excrescence, and the origin appeared to be from the mucous surface. There was no naked-eye appearance of epithelioma,

Digitized by Google

but since, according to Lebert, epithelioma develops in 12 per cent. the lip was removed with a margin of sound skin around the growth and healed subsequently without trouble. There was no glandular affection and no sign or history of syphilis. I made no section of the lip, as it was preserved for museum purposes. Like most platelayers the patient smoked much.

Carlisle.

CASE OF SEVERE HEAT-STROKE; RECOVERY.

BY J. W. CRAWSHAW, M.B., CH.B. VICT.,
LATE SURGEON, OCEAN STEAM NAVIGATION COMPANY.

IN THE LANCET of April 4th Mr. P. J. Atkey reported a case of severe heat-stroke in which the temperature reached 108·2° F. and the patient recovered without any ill effects. In May, 1894, while acting as surgeon on board the Ocean Steam Navigation Company's s.s. *Pyrrhus* I had a somewhat similar case, which recovered very rapidly. The following account of the case is taken from my entries made at the time in the surgeon's log-book.

On May 28th, 1894, while in the Indian Ocean some 300 miles to the westward of Ceylon an English youth aged seventeen years was taken ill. He had been working nearly the whole day directly exposed to the heat of the sun. He never complained of any illness, but at 4.30 P.M. he was noticed to stagger and fall. Some of the men went to his assistance, found him very ill, and at once sent for me. I found him quite conscious, and he complained of violent headache and pains in the back and limbs. His skin was very hot and dry and his pulse was very rapid, full, and bounding. I placed my thermometer beneath his tongue, but by the time the temperature was taken he was quite comatose. The thermometer registered 108°. The method I adopted to reduce the temperature was very rough and simple, but proved very effective. I had the lad stripped as rapidly as possible and laid on the deck. A large piece of ice was placed to his head and sea water was brought in buckets and dashed over him in an almost continuous stream. After about twenty minutes of this treatment the temperature had fallen to 103° and the lad had recovered consciousness and expressed himself as feeling much better. The douching was discontinued, he was placed in his bunk and given hot tea to drink. A powder consisting of five grains of calomel and twenty grains of antipyrin was given. An hour later I found the patient's temperature had again risen to 105° and he was very drowsy. He became unconscious again and had a violent convulsion. The cold douching was recommenced in the same manner and continued for some time until the temperature fell to 100·4°. He again recovered consciousness and was placed under awnings on the hatch, where he was much cooler than in the forecastle. He felt much better and was able to partake of a little milk food. The temperature afterwards rose to 103°, but no higher. The skin continued hot and dry and a diaphoretic mixture was given. He passed rather a restless night, but on the next morning, the 29th, he felt fairly comfortable. His temperature was 101°. He had micturated very frequently during the night and the skin was still very dry. The bowels had not been moved, so two ounces of mistura sennæ composita were given. At 9 P.M. the temperature was normal. On the 30th he was much better. The temperature was normal the whole day and the skin moist. The bowels were well opened. On the 31st he felt quite well. He had no headache, dizziness, or other unpleasant symptom, and was allowed to resume his work. Throughout the remainder of the voyage he remained perfectly well, but was careful not to expose himself to the sun.

I can quite endorse all that Mr. Atkey says about the good chance these cases have on board ship. The surgeon cannot be far away and ice and water at a suitable temperature are plentiful. Much delay in a case like the above would greatly diminish the prospects of recovery. From the time when the patient was first noticed to be ill to the commencement of the douching ten minutes could not have elapsed, and it was undoubtedly this prompt treatment which saved his life. Dr. Wales of Canton was on board at the time and his experience of these cases was of great assistance to me.

LONDON HOSPITAL.

A CASE OF CHRONIC INVERSION OF THE UTERUS; CIRCU SCRIBED SLOUGHING CAUSED BY AVELING'S REPOSITOR; SUBSEQUENT REDUCTION.

(Under the care of Dr. HERMAN.)

THERE appears to have been some uncertainty about th cause of the inversion in this case, and it is not possibl now to say definitely what produced it. The treatment b Aveling's repositor was effectual as it has proved in so man cases recorded in our columns, but in this instance it pro duced a limited slough of the uterus. There are two impor tant points to bear in mind when applying continuous elasti pressure for inversion: the pressure must act in the line o the axis of the inverted uterus and likewise of the axis of the pelvic brim and there must be effective counter pressure. Again, the pressure must be carefully regulated and the apparatus replaced in position as often as the restlessness of the patient makes it necessary. If these precautions are taken the inversion will usually be reduced in a few days, although in one recorded instance reduction was not effected for three weeks. For the notes of this case we are indebted to Dr. G. H. Cowen, resident accoucheur, and Mr. E. C. Davenport, clinical clerk.

The patient, aged thirty-one years, was admitted on Dec. 31st, 1895. She said that she had always enjoyed good health until her last confinement five month ago. On this occasion (the seventh) the child was a large one and was delivered by forceps. Mr. Alexander of Bromley, E., who attended her, stated that he noticed no inversion at the time, although he gave a uterine douche after delivery. He did not see her again until the day before her admission to the hospital. The patient said that she got up on the eighth day after delivery, and while the bowels were acting "the womb came down." She replaced it herself, but lost a good deal of blood. She had no further trouble for three weeks. Then the womb "came down" again. After this she had no inconvenience except a watery discharge until a fortnight before admission, when she had severe floodings. She went to a medical man who tried to get the womb back, but failing to do so advised her to go to the hospital. She had nursed her child until three weeks before admission. On vaginal examination there was found to be a round swelling about the size of a Tangerine orange projecting into the upper part of the vagina. It presented no opening. The sound could not be passed up by its side, nor could the body of the uterus be felt bimanually in its proper place. The urine was alkaline and ammoniacal, with a deposit of pus and phosphates. There was no other sign of disease. On Jan. 6th, 1896, Aveling's repositor was applied. Its pressure caused much pain and made the patient restless, for which reason, probably, it slipped off the fundus. Between the 6th and 20th it was frequently applied, but each time was found to soon slip off without reducing the inversion. On the latter date it was found that there was much greenish, offensive discharge, and on this account the repositor was discontinued and an antiseptic vaginal douche given every six hours. On Feb. 11th the discharge had almost ceased. On examination the inversion was found to be less complete than at first, and a loss of substance could be felt at one part of the fundus. The repositor was reapplied. On the 12th the fundus uteri was in the normal position and there was no discharge. On the 20th the patient was discharged well.

Remarks by Dr. HERMAN.—The uniform success of Aveling's repositor in the treatment of chronic inversion of the uterus makes it important both to strengthen the evidence that this treatment of the rare displacement in question is the right one, and to publish cases which aid sound judgment as to the

Digitized by Google

possible ill results of the use of the instrument. Here local sloughing resulted from its pressure; but when the pressure was discontinued and suitable treatment employed the slough was separated, the part brought into a healthy state, and then the instrument was reapplied with success. The cause of the inversion was in this case a mystery, as the patient had not been under medical observation during the time between her delivery and her admission to hospital. Communication with the medical man who attended the patient in labour seemed to make it certain that the inversion was not puerperal. There may have been a fibroid which dragged down the fundus and was spontaneously separated before the patient's admission. But as no fibroid was seen this is only a conjecture.

SHEFFIELD GENERAL INFIRMARY.

A CASE OF EXTENSIVE WOUND OF THE ABDOMEN.

(Under the care of Mr. ARCHIBALD CUFF.)

OF the many painful methods devised by man for self-destruction that of abdominal section is surely one of the most curious; and that it may not always prove an effectual means to an end the following case will show. In the instance of a stab wound of the abdomen a surgeon may have a little hesitation before he decides whether he will operate or not, but with a condition such as is described below there is no question as to the need of surgical interference. The indications are clear and cannot be mistaken. It is necessary to act in these as in all wounds: to arrest hæmorrhage, to cleanse the wound efficiently, &c. But beyond the immediate arrest of any hæmorrhage it may be possible to do little until the patient has somewhat recovered from his shock. This case well illustrates how the various difficulties may be successfully overcome. Extensive injuries such as this are not very common, but we may refer to others of comparatively recent occurrence which somewhat resemble it. Langenbuch[1] had a young man under his care who had been severely wounded in the abdomen by a waggon pole. The exposed intestines were much soiled and bruised; in some places the muscular and serous coats were lacerated. The intestines and peritoneum were carefully cleansed and the wound was closed, the patient making a good recovery. Stimson[2] treated a youth aged eighteen years who had been stabbed below and to the right of the umbilicus. There was a considerable quantity of blood in the peritoneum and three wounds of the intestine, two wounds of the omentum, and one of the mesentery. The patient recovered after operation and suture of the various wounds. Dr. Clark[3] has recorded a recovery after the removal of one-third of the omentum. The abdominal wound was five inches long, and the entire small intestine with some of the omentum and colon protruded. A quantity of shavings was found in the omentum. The patient was quite well three years after the operation. After a large wound such as that encountered in the present case, especially considering the direction of the incision, we must anticipate the eventual formation of an abdominal hernia; this does not, however, alter the fact that the man's life was saved by the skilled treatment of those under whose care he was in the infirmary. For the notes of the case we are indebted to Mr. Archibald Cuff, resident medical officer, under whose care, by the courtesy of Mr. G. H. Shaw, senior surgeon to the institution, the patient was.

A man thirty-three years of age, when attired only in his rather dirty shirt, drew a razor horizontally across his abdomen on the morning of March 15th. The resulting wound, commencing on the left as far out as and about one inch above the anterior iliac spine, and ending on the corresponding spine of the opposite side, completely severed all the abdominal muscles in its entire length, the peritoneum being cut through for the middle five and a half inches. This happened about 9.45 A.M. The man on being found unconscious was sent to the infirmary, arriving about 11 A.M., when the wound was found to gape widely, the recti muscles having retracted considerably; the intestines were almost wholly lying outside the body, in which condition they had been, at any rate, whilst the patient was in the cab which brought him. His condition at this time appeared to be desperate, the collapse being extreme: the breath was taken in sighing gasps at intervals, the pulse was imperceptible at the wrist, and the skin was cold and clammy to the touch. The intestines were protected with large marine sponges wrung out of a 1 in 2000 solution of mercury perchloride and efforts were made to revive the patient. A hypodermic injection of one-twentieth of a grain of strychnine was given, and as it was considered, from the quantity of blood clot lying upon the intestines and in the pelvis and from the general state of the patient, that the hæmorrhage had been severe, infusion of normal saline solution was thought to be indicated. This was quickly done by Mr. Rutherford, and about thirty-six ounces of fluid at a temperature of 108° F. were infused into the patient's system by way of the median basilic vein. The reaction to this treatment was prompt, the pulse becoming full and countable and the respiration, though shallow, more frequent and regular, and the patient showing by his movements that he did not quite appreciate the efforts that were being made. During this time the skin of the abdomen was disinfected to some slight degree by being scrubbed with a 5 per cent. solution of carbolic acid and the wound was surrounded with sterilised towels. The intestines, which up to this point had been protected with flat sponges, were now examined to ascertain if they had sustained any injury, but happily none was found; they and the pelvis, which contained a good deal of blood clot, were then cleansed and swabbed with the perchloride solution and the peritoneum dried as thoroughly as possible. At this stage the severed epigastric arteries began to bleed, and all four ends were secured and tied. The peritoneum was then brought into apposition with fine silk sutures, and after this the various layers of the abdominal wall were brought together with the same material. The greatest difficulty in this part of the proceedings was associated with the endeavour to bring the ends of the recti and their sheaths into apposition, the strain upon the sutures being very great. Finally, silkworm gut was used for the cutaneous sutures. After plentifully sprinkling the wound and its neighbourhood with iodoform the usual dressings were applied. The iodoform was not used from any idea of its antiseptic properties, about which some people are now rather sceptical, but on account of its very useful property as a powder of absorbing discharge and so leaving an arid and inhospitable dwelling-place for any cocci which might come out of the neighbouring hair follicles unscathed when the storm of antiseptics should have passed over. The hopes in this direction were quite fulfilled, for the gut stitches were removed on the tenth day, the skin wound having healed by first intention, and with the exception of a small abscess in connexion with one of the deep stitches in the angle of the wound which developed later all continued to progress favourably. The patient's after-history is briefly as follows. On his removal from the table collapse, though to a lesser degree, was again apparent and was met by a rectal injection of a pint of hot coffee, by the administration of more strychnine, and by brandy given by the mouth. He quickly rallied and the pulse-rate and temperature, which were then 140 and 97°, became more favourable, and at 6 P.M. were 118 and 102° respectively. The patient perspired profusely. From this time he never retrogressed, the temperature falling and remaining at a fairly normal level for the next ten days, when it rose to 100·8° on the occurrence of the small abscess and then gradually fell again. As regards treatment, the bowels were kept open with copious enemata given on the first, second, and fourth days. This was regarded as being very important in order not to allow any stagnating fæces to remain in contact with walls whose peritoneum might be weak in protective properties. Up to late on the first evening only warm water and a little brandy were allowed to be given. After this, milk well diluted, meat juice, ice, brandy, and barley water were frequently given in small quantities. Milk appeared to produce vomiting, and malted milk was substituted with advantage for a few days. This restricted diet at the end of a week was gradually replaced by an ordinary one. The patient was allowed to sit up in bed on the sixteenth day and was up and dressed on the twenty-eighth day.

Remarks by Mr. CUFF.—The case, I venture to think, is interesting on account of its initial severity, for the man, after inflicting a severe wound, was more than an hour without treatment, was brought to the infirmary in a jolting cab, and appeared to be *in extremis* on his arrival. The

peritoneum seems to have been a patient and long-suffering membrane not to have taken exception to all this rough treatment, for at no time was there the slightest evidence of peritonitis. Another point of interest was the success of the two methods of filling and stimulating the vascular system—i.e., by venous infusion and by rectal injection. The effect of both was very marked, and in the case of the first almost immediate, in the second appearing in about ten minutes. I would call attention to what has been insisted upon by Dawburn, McBurney, and others—namely, the importance of having the normal saline solution really hot, as hot as the hand can comfortably bear. The stimulating effect of infusion is then much greater and more lasting than that produced by solutions at 100°, the temperature generally advised.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Use of Guaiacum in the Treatment of Chronic Gouty Affections and its Value in Warding off Acute Attacks.

AN ordinary meeting of this society was held on May 26th, Dr. W. HOWSHIP DICKINSON, President, being in the chair.

Sir ALFRED B. GARROD read a paper on the Use of Guaiacum in the Treatment of Chronic Gouty Affections and its Value in Warding off Acute Attacks. He first alluded to a communication to the Royal Medical and Chirurgical Society on Feb. 8th, 1848, entitled "Observations on the Pathological Condition of the Blood and Urine in Gout, Rheumatism, and Bright's Disease," in which he had the privilege of demonstrating the presence of uric acid in the blood and also the relation between uric acid and gout, and many other points; these were referred to as they bore upon the present paper, the chief object of which was to direct the attention of the society to the value of guaiacum in the treatment and prevention of gout. The name guaiacum was given to the resin of a tree called *Guaiacum officinale*, the wood of which was termed lignum vitæ. After speaking of numerous observations carried on for very many years among both hospital and private patients with guaiacum, both in the form of a powder and as ammoniated tincture of guaiacum, Sir A. B. Garrod thought that he had been successful in establishing the following points in regard to the action of guaiacum: 1. Guaiacum was innocuous, and might be taken for an indefinite period of time, and, looked upon as a condiment rather than as a drug, as harmless as ginger or any other condiment. 2. Guaiacum possessed a considerable power, but less than colchicum, in directly relieving patients suffering from gouty inflammation of any part; it might be given whenever there was but little fever. 3. Guaiacum taken in the intervals of gouty attacks had a considerable power of averting their recurrence; in fact, it was a very powerful prophylactic. 4. Guaiacum did not appear to lose its prophylactic power by long-continued use. 5. There were a few persons who could not readily continue the use of guaiacum; for such cases there were other drugs whose action was in some respects similar as prophylactics—perhaps serpentary was one of the most powerful of these. Sir A. B. Garrod gave a short account of serpentary, and mentioned the fact that he had given it successfully in gouty inflammation in the elderly subject; as a prophylactic he had less personal experience, but he doubted not that it was possessed of considerable power. Before attempting to explain the mode of action of guaiacum in the treatment of gout, he gave his view of the origin of uric acid in the animal economy; instead of supposing that it was formed in the system by the metabolism of the nitrogenised tissues, and then thrown out by the kidneys, he was of opinion that it was produced from urea and other nitrogenised bodies in the blood by the direct action of the kidney, and that when uric acid was contained in the blood this arose from the absorption from the kidney structures of the urate of ammonium, depending on the want of sufficient throwing-off powers from these tissues. He was aware that it was from his own discovery of uric acid in the blood that the opposite view of the formation of uric acid arose. To explain the prophylactic action of guaiacum he did not think that it affected the formation of uric acid, but that it acted directly on the kidney itself as a stimulant and enabled it to get rid of any accumulation in the tubules and thus prevented absorption from them into the blood. In confirmation of this view it was found that patients when taking guaiacum often had unusual deposits of urates in their urine. The paper closed with the following remarks: "If the statements contained in this communication had the effect of inducing his medical brethren to direct their attention to the value of guaiacum in the treatment and prevention of gout he felt he should have conferred some benefit on the profession and through them on the public at large."

Dr. NORMAN MOORE said that Sir A. B. Garrod was the first to lay down the definite knowledge which enabled physicians to say for certain post mortem that a given patient had or had not suffered from gout. At St. Bartholomew's Hospital a very large number of cases of gout were met with, possibly because they were close to the Central Meat Market. He had seen at least 100 instances post mortem of persons displaying the features in morbid anatomy which Sir A. B. Garrod had shown to belong to this disease. Colchicum might be given for long periods with advantage and some success in warding off the attacks. Though some of the success might be due to care in diet he did not think it was entirely due to this, because persons who suffered from the most inveterate gout passed through fewer attacks when taking small doses of colchicine over long periods. He asked Sir A. B. Garrod what was the true history of the reputation of guaiacum in former times. At the earlier part of the seventeenth century guaiacum was extolled as the most successful remedy for what we should call tertiary syphilis. He wondered if its reputation was due in part to its effect on sore-throat or perhaps part of the pain that the patients suffered was gouty. Indeed, it was possible that guaiacum was successful in postponing or altogether preventing further attacks of pain which were not really syphilitic, but gouty.

Dr. CALDWELL (New York) held that "poor man's gout" required a different treatment from "rich man's gout," the former requiring stimulants, and he advocated "sweating it out." He asked Sir A. B. Garrod if it were not possible to secure the elimination of the *materies morbi* at the site of its deposit.

Dr. MURRELL said that he could support Sir A. B. Garrod's conclusions as to the efficacy of guaiacum in chronic gout. He had used guaiacum during the last six years at the Westminster Hospital, not only for chronic gout, but for rheumatism, tonsillitis, and chronic bronchitis associated with the gouty taint. The Throat Hospital lozenges he had found useless, because the dose was too small and lozenges were too expensive for out-patients. The taste of the mixture of the British Pharmacopœia was so atrociously nasty that patients declined to take it. The tincture was difficult to dispense because it did not mix with water, and so he made a confection containing ten grains in a drachm of honey, the patient taking one or two drachms three times daily immediately after meals. Though this was efficacious, yet it presented disadvantages, for it acted as a powerful purgative and brought out a rash like that of a copaiba, but not attacking the face; it was accompanied with much itching. The drug sometimes caused burning feelings in the throat with a sensation of constriction, but this was overcome by giving the resin with half an ounce of extract of malt. He had also given it mixed with an equal amount of confection of sulphur. Though he had come to the same conclusion as Sir A. B. Garrod he felt he had been working on different lines, for he had made use of guaiacum resin; he had given it alone instead of in combination with cinchona, iodide of potassium, or colchicum; he had given it also in much larger doses—namely, twenty grains of the resin three times a day, the resin being of about four times the strength of guaiacum itself. He had not given guaiacum in cases of acute gout, but he had given colchicum wine with iodide of potassium three times daily. Recently he had used a liniment consisting of half an ounce each of iodide of potassium, methylated spirit and soap liniment, with oil of cajuput and oil of cloves. A piece of lint steeped in this liniment was applied to the affected joint with good results. He had no doubt as to the efficacy of guaiacum in warding off attacks.

Dr. HAIG said that while he agreed that guaiacum tended to ward off gouty manifestations he did not concur as to the way in which the drug acted. Iodide of potassium provoked diuresis and dilatation of all the bloodvessels with a fall of blood pressure. Lithia and ammonia

Digitized by Google

had a similar action, as also had copaiba, tar, cannabis indica, certain salts of calcium, and certain bitters, such as chiretta, gentian, and possibly serpentary. Copaiba contained a large quantity of acid and guaiacum agreed with it in this. He believed that all these drugs diminished the excretion of uric acid and kept the blood clear of it, and he had explained fully elsewhere the method of action of some of those drugs. He was interested in what had been said about the effects noted by Cullen and other physicians of his time because it agreed with his view that these drugs suppressed gout, but did not cure it. He accepted the view that urate of ammonia was not formed from urea in the kidneys, but that the reverse took place. Much of the uric acid met with in disease was not formed in the system, but was introduced with animal food.

Dr. EWART said that he had been in the habit of giving guaiacum in conditions akin to gout, and he had been struck by the effect which it exerted upon the condition of the patient. He thought that the action of guaiacum upon the capillaries was not limited to the kidney, but extended to the whole system and in particular to the capillaries of the muscles; indeed, the effect of guaiacum in relieving painful manifestations located in the muscles was well known. Taking into consideration the bulk of the muscular system it was easy to imagine that any interference, however small, with its metabolism must have an appreciable effect upon the juices, and as to the glandular system guaiacum acted in that direction also, and was a recognised hepatic stimulant. If the drug were used over a long period in doses sufficient to cause a laxative action this would influence the health of gouty persons very materially. He had found tincture of iodine very useful in combination with guaiacum.

The PRESIDENT said that the treatment of rheumatism by guaiacum was a very old practice; it had been used at St. George's Hospital for at least a century, and the method was certainly much more successful than others in use at the early part of this time. The treatment of acute rheumatism by guaiacum had been continued until the last twenty years, and even now it was used for chronic rheumatism. From his own experience he could speak very strongly as to its value in some forms of acute rheumatism as well as in gout. With regard to the relation of uric acid to gout he placed himself in the position of a disbeliever. There was no doubt of its presence, but he preserved doubts as to its being the real cause; was it not what we might call a by-product? During convalescence from scarlet fever when nephritis was present it was not uncommon to find enormous quantities of uric acid passed, but that did not necessarily lead to gout.

Sir A. B. GARROD, in reply, said that with regard to the absolute and necessary connexion between gout and uric acid one never missed finding urate of soda deposited in the tissues after even the slightest attack of gouty inflammation. He admitted the value of guaiacum in acute rheumatism, but many cases formerly treated as acute rheumatism were really instances of acute gout. Though many pains formerly treated as syphilitic were possibly gouty, yet he was convinced also that guaiacum would relieve muscular pains which were not gouty. Though he had frequently prescribed this or that drug in combination with guaiacum he did not commonly give many together. As healthy normal skin could not secrete uric acid, he could not advocate "sweating the disease out." He was convinced that there could be no gouty symptom without the presence of urate of sodium in the blood and this had no relation to the amount thrown out by the kidneys. Guaiacum might act by increasing the amount excreted, causing visible deposit in the urine, to which the patient would call attention.

CLINICAL SOCIETY OF LONDON.

Typhoid Fever with Hyperpyrexia and Cardiac Dilatation.—Chronic Dilatation of the Colon.—Central Sarcoma of the Femur with Early Dissemination.

THE annual general meeting of this society was held on May 22nd, Dr. BUZZARD, President, being in the chair.

Dr. A. H. W. CLEMOW related a case of Typhoid Fever associated with Hyperpyrexia and Acute Cardiac Dilatation in which venesection was performed. The patient, a man aged twenty-five, became ill on Nov. 13th, 1895, and when first seen on the 18th his temperature was 104° F. (although he had been taking antipyretics for two days or more), and fine crepitations were audible at the base of the right lung. On the 19th epistaxis occurred and the following day after a dose of calomel (3 gr.) typhoid stools were passed. He was placed upon an appropriate dietary of milk (two and a half pints per diem) and beef-tea (one and a half pints) and brandy, and ordered cold or tepid sponging at frequent intervals, as the temperature might indicate. During the next four days the temperature ranged between 102° and 104°. Retention of urine occurred during the night of the 25th, and was relieved by a gum elastic catheter on the morning of the 26th, and again at 9 P.M. His condition at the time was otherwise satisfactory; the pulse was 90, the tongue was moist and not excessively furred, and there was no abdominal distension. At 10 P.M. and 11.45 P.M. epistaxis recurred. The temperature at midnight was 103·4°. Two hours later there was a severe rigor, the patient became wildly delirious, and the axillary temperature rose to 106·7°. Vigorous iced sponging reduced this to 103°, and he became quiet, though he continued unconscious. At 7 A.M. his temperature was normal, but at 7.30 there was another rigor with delirium, and the axillary temperature rose to 107°. Iced sponging again lowered the temperature and quieted the delirium. At 9.30 A.M. he was seen in consultation by Sir William Broadbent, who advised the subcutaneous injection of one-third of a grain of morphia. Between 11 and 11.30 A.M. a rapid change for the worse occurred and Dr. Clemow was requested by the nurse to come at once as the patient was sinking rapidly. On his arrival the patient was found to be apparently in "articulo mortis"—the face was deeply cyanosed, the jaw had dropped, conjunctival reflex was absent, and respiration consisted of almost futile inspiratory efforts. Examination of the heart revealed a very considerable distension of the right side of acute onset. Venesection from the left median basilic vein was at once resorted to, eight ounces of blood being removed, and subcutaneous injections of digitalin (gr. $\frac{1}{100}$) and strychnia (gr. $\frac{1}{30}$) and brandy administered. The cyanosis then gradually diminished, the pulse, although very feeble and irregular for a few minutes, became fuller and less rapid, and shortly the respiratory movements improved, air entering the chest more readily. An hour later, and subsequently every three hours for the next twenty-four hours, the injection of digitalin and strychnia were repeated, and were supplemented by enemata of peptonised milk, beef-tea, and brandy. About five o'clock the patient regained consciousness and was able to take some nourishment. The next day considerable hypostatic congestion of the lungs manifested itself, but passed off under appropriate treatment. During the remainder of his illness rigors threatened on two or three occasions, the temperature rising to 103° or 104°, but the patient ultimately made a complete and perfect recovery.—Dr. CHAPMAN remarked that it was worthy of note that not only was venesection successful in reducing the temperature, but that antipyretic remedies had failed to do so.—Dr. F. L. BENHAM said it was doubtful to what degree the venesection had benefited the hyperpyrexia *per se*, or how much the improvement was due to relief given to the pulmonary complication by blood-letting. In one case of rheumatic hyperpyrexia, which after the third day from admission could not be controlled by ordinary antipyretic means such as cold, he employed venesection as a last resource, but with no improvement. The rigors might have indicated advancing pulmonary inflammation.—Dr. SAMUEL WEST remarked that rigors frequently followed hyperpyrexia. The bleeding was a great relief to the over-distended right ventricle and it acted in a mechanical way; the amount of blood let should depend upon the bulk of the patient. It would certainly not, as a rule, reduce pyrexia. There were comparatively few cases in which bleeding was admissible, but in these it was often not performed when it ought to be.—Dr. CLEMOW, in reply, said that he gave the patient no antipyretic remedies beyond cold sponging, which never failed to keep the temperature down. The rigors he regarded as due to the severity of the enteric fever. The venesection was done solely to relieve the over-distension of the right heart. He mentioned the case of a woman who was suffering from uræmia within a few hours of her delivery. She had marked orthopnœa and was very deeply cyanosed. Venesection to the amount of twelve ounces was practised and was followed by rapid and complete relief, delivery being afterwards effected, and the patient recovered.

Dr. ROLLESTON and Mr. HAWARD brought forward a case of Chronic Dilatation of the Colon. A boy aged twelve years had been subject to constipation since six months of age. He

Digitized by Google

came from Inverness, and porridge had formed a considerable part of his diet. From time to time he had attacks of vomiting and complete inactivity of the bowels, on one occasion having gone for nine weeks without an evacuation. On admission to St. George's Hospital he was seen to be emaciated, the eyes sunken, and the complexion of a bistre tint. The abdomen was enormously distended, and through the stretched abdominal wall peristaltic contractions of the intestine could be seen. The front and upper part of the abdomen were resonant and no fæcal masses could be felt. Palpation of the abdomen usually gave no pain, but sometimes, on deep pressure, he complained of tenderness, the situation of which varied. The rectum was natural and there was no spasm of the sphincter. During the three months that he was under observation his condition varied, often very suddenly. He would improve for a time, the bowels acting daily and the abdomen becoming soft. Then suddenly constipation and vomiting would come on without manifest cause. These attacks usually subsided in a day or two, but in one of them he died. There was never any obstruction, the bowels acted nearly every day. The treatment was varied, but, with the exception of calomel, nothing seemed to do any material good. At the necropsy great dilation of the colon was found; the ascending colon passed up to the hepatic flexum, from which point the transverse colon descended to the neighbourhood of the cæcum; the descending colon occupied the greater part of the right half and upper portion of the abdomen; it passed out of sight in the left lumbar region, and then joined the dilated sigmoid flexure. No stricture or cause for obstruction could be found anywhere. There were numerous ulcers in the colon, due, presumbly, to distension; the muscular coats were hypertrophied. Cases of dilatation of the colon were divided into acquired and congenital, and reference was made to nine cases, eight of which were fatal. The etiology and pathology of the condition were discussed, and it was shown that neither mechanical causes nor an inflammatory origin were borne out by facts. The high mortality and the unsuccessful results of treatment were pointed out and the danger of massage insisted upon. The question of colotomy or of opening the small intestine was considered, and it was advised that, having regard to the abnormal mobility and change in the position of the bowel, any operation should include as its first step the ascertainment of the anatomical relations of the parts involved.—Dr. HALE WHITE said that he agreed in the correctness of the classification. The acquired form, due to constipation, was common, and as it was well recognised it was not of much importance. Of the congenital form several cases were found scattered through medical literature. For these there was no satisfactory explanation whatever, the constipation being a result rather than a cause. Some of the cases of dilatation of the colon, particularly of the sigmoid, occurred in adults and were not associated with sufficient constipation to account for the dilatation. These cases appeared to him to be comparable to cases of paralytic distension of the stomach; they were equally common in men and women. Treatment by opening the large bowel above the distended part had been practised, so as to allow the fæces to pass, the portion of bowel below being regularly washed out and left to rest.—Mr. BRUCE CLARKE said that besides the case recorded by Dr. Herringham and himself he could mention another instance which he believed to be in the same category. It was that of a man who had obstruction of the large intestine which was thought to be carcinomatous. Colotomy was performed and the patient improved and lived for four years, dying ultimately of a condition unconnected with the bowel.—Dr. ROLLESTON, in reply, said that the case recorded by Osler was the only one which had not proved fatal. As in these cases the colon was so movable it was suggested that exploratory laparotomy should be first done, as otherwise when lumbar colotomy was performed the surgeon might fail to find the bowel.

Mr. G. R. BALDWIN read the notes of a case of Central Sarcoma of the Femur with Early Dissemination. The patient, a man aged thirty-five, was admitted into St. George's Hospital on Sept. 3rd, 1895, with a central sarcoma of the femur. The thigh was amputated and the man discharged on Oct. 2nd. Soon after leaving the hospital he suffered from pain in the right arm, which subsequently became stiff and weak. On Nov. 1st he found on waking that he was paralysed over the lower part of the trunk and lower limbs. He was re-admitted on Nov. 8th, the trunk, the left lower limb, and stump being paralysed and devoid of sensation. He was suffering from incontinence of urine and fæces. The right arm was completely paralysed and the left partially; both upper extremities were without sensation save over the deltoid muscles. He died two days after admission. A post-mortem examination was made and widely disseminated growths were found. Of these the largest was one growing from the seventh cervical vertebra and extending upwards and downwards in front of the lower cervical and upper dorsal vertebræ, the lower cervical nerves being embedded in its substance. Other growths were present in both lungs and in the right kidney. Both primary and secondary growths were mixed-celled in nature. Mr. Baldwin also referred to a second case in which a central sarcoma of the femur became disseminated. Unfortunately, there was no record of the nature of the growth and no post-mortem examination was made.

The business of the annual general meeting was then proceeded with. A satisfactory report from the council was read. The membership now numbered 568. A committee of the society had been appointed to make an index to all the volumes of Transactions which had been issued by the society, of which Dr. A. E. Garrod was secretary.

The committee appointed to investigate the clinical value of the antitoxin of diphtheria hoped to be able to present their report during the coming year, and they added that they felt that the necessity for the present inquiry had not been affected by the publication of reports on the use of antitoxin either in this country or abroad. The financial statement showed a comfortable balance on the right side.

The customary votes of thanks to the retiring officers having been giving, the result of the ballot for the election of officers and council for the year 1896-97 was declared as follows: — President: Thomas Buzzard, M.D. Vice-Presidents: Thomas Barlow, M.D., Frederick Taylor, M.D., Thomas T. Whipham, M.D., William Henry Bennett, F.R.C.S., Rickman John Godlee, M.S., and William J. Walsham, F.R.C.S. Treasurer: William Miller Ord, M.D. Council: W. H. Allchin, M.D., W. P. Herringham, M.D., Constantine Holman, M.D., Patrick Manson, M.D., Sidney Martin, M.D., F. W. Mott, M.D., F. G. Penrose, M.D., Seymour J. Sharkey, M.D., E. Markham Skerritt, M.D., W. Hale White, M.D., Dawson Williams, M.D., W. Bruce Clarke, M.B., A. Pearce Gould, M.S., C. R. B. Keetley, F.R.C.S., C. B. Lockwood, F.R.C.S., Rushton Parker, B.S., Bilton Pollard, F.R.C.S., A. Q. Silcock, F.R.C.S., M.S., W. G. Spencer, M.S., and J. Bland Sutton, F.R.C.S. Honorary Secretaries: G. H. Makins, F.R.C.S., and J. Kingston Fowler, M.D. Trustees: Christopher Heath, P.R.C.S., William Miller Ord, M.D., and J. Burdon Sanderson, M.D.

BRITISH GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—The Treatment of Carcinoma and other Diseases by Animal Extracts.

A MEETING of this society was held on **May 14th**, Dr. C. H. F. ROUTH, Vice-President, being in the chair.

Dr. F. F. SCHACHT showed a specimen of Unruptured Tubal Gestation containing a Fœtus of about six weeks' development.—Dr. HEYWOOD SMITH and Dr. J. A. MANSELL MOULLIN made some observations, and the specimen was referred to a sub-committee to be reported upon.

Mr. F. BOWREMAN JESSETT showed a specimen of Multilocular Cyst of the Omentum. It was uncertain whether the cyst was originally omental or whether it was a vagrant ovarian cyst which had formed a secondary attachment to the omentum. The specimen was referred to a sub-committee.

Dr. ROBERT BELL (Glasgow) read a paper upon the Treatment of Carcinoma of the Uterus, Certain Forms of Ovarian Disease, and Fibroids of the Uterus by means of Thyroid, Parotid, and Mammary Gland Therapeutics. Judging from the beneficial effects which thyroid extract exerts upon the epithelium of the skin in psoriasis, Dr. Bell was led to infer that epithelioma of the cervix uteri might be due to the absence of some obscure catalytic action of this gland, and that thyroid extract might consequently be useful in the treatment of epithelioma of the cervix and of other unhealthy conditions of mucous surfaces. In his experience metrorrhagia was frequently associated with unhealthy conditions of the thyroid gland. He regarded lesions of the

Digitized by Google

cervix uteri, such as lacerations and hypertrophy due to endometritis, as the predisposing cause of malignant disease, and from his experiments he concluded that the exciting cause existed in an abnormal condition of the thyroid gland. It would further appear that the parotid gland exerted a powerful influence upon the ovaries; and though not able to judge whether ovarian disease was super-induced by any lack of influence of the parotid he was able to vouch for the fact that ovarian disease could be brought under subjection by the administration of parotid glands of healthy young sheep, calves, and pigs. Again, he regarded it as beyond dispute that fibroids of the uterus, as well as hyperplasia and flaccidity of the organ, could be beneficially affected by the employment of mammary glands of healthy animals. He had also ascertained that ovarian disease was beneficially influenced by the administration of mammary gland. He then gave the history of three cases of epithelioma of the cervix treated by thyroid extract, two cases of uterine fibroids and two of menorrhagia treated by mammary palatinoids, and four cases of ovarian disease treated by parotid palatinoids, all treated within the last six months, except the first case of epithelioma, which dated from last summer.—Mr. BOWREMAN JESSETT thought the comparison of epithelioma with psoriasis and myxœdema had no rational basis. He noted that in all the cases of epithelioma curetting was done, followed by the application of such strong caustics as chromic acid and chloride of zinc, and he was inclined to attribute the improvement to the use of the caustic. The results would be more convincing if no local measures had been adopted. As regards fibroids, it was well known that they were apt to get smaller under the influence of rest and the menopause. Dr. Bell's cases were too recent for the deductions to be regarded as conclusive. The cases of ovarian disease were also treated locally by means of iodised phenol and ichthyol tampons, and these means alone were generally found sufficient. No doubt, however, many would give these new methods a trial.—Dr. LEITH NAPIER said he had no experience of this treatment, but he had recently read a paper by a Dr. Jouin who, in one case, was treating a patient for obesity by means of thyroid extract. She happened to have a fibroid, and at the end of twelve months he discovered that it had shrunk from two inches above the umbilicus to one inch above the pubes. This led him to try it in other cases. The second, a soft fibroid, was benefited; the third, a hard fibroid, was not. Three other cases were too recent to draw conclusions from. The recent views of the pathology of soft fibroids regarded them as associated with morbid glandular action, so it was quite possible that thyroid extract might exert an influence over them.—Dr. HEYWOOD SMITH observed that Dr. Bell did not tell them what was the condition of the cervix in the first case at the time of the last examination, but in all cases there seemed to have been an amelioration of symptoms in a much shorter time than they were accustomed to. It would be useful to know whether any of the cases were treated by animal extracts alone and what led Dr. Bell to decide which extract to employ in any given case. In view of the results recorded in the paper he thought they should give the method a trial.—After some remarks by the CHAIRMAN and by Dr. MACAN, Dr. BELL replied. He thought Mr. Jessett was under a misapprehension in thinking that he compared epithelioma to psoriasis. It was rather that in view of the action of the thyroid extract on the epithelium in psoriasis he thought it might also have a good effect in epithelioma. He used mammary extract for fibroids because the mamma and uterus were in close physiological sympathy; whilst the physiological relation between the parotid gland and the ovaries, as shown by the frequent metastases between the two, led him to give parotid extract in ovarian disease. He felt sure that those who tried the method would be satisfied with the results.

PATHOLOGICAL SOCIETY OF MANCHESTER.

Exhibition of Specimens.—Arseniuretted Hydrogen Poisoning.

A MEETING of this society was held on May 13th, Dr. H. R. HUTTON, President, being in the chair.

Dr. PETER THOMPSON showed specimens of Hydatid Cysts affecting the liver and transverse mesocolon. The liver was the seat of extensive growths, there being five distinct tumours in various stages of activity. Two had suppurated, two had died and had been converted into inert masses, whilst the fifth cyst was in the active growing stage. The tumour found in the transverse mesocolon was about the size of a small orange. It was easily felt through the abdominal walls and was freely movable to all parts of the abdominal cavity. It was quite hard and solid and on section the interior showed a large number of opaque membranes, the walls of shrunken daughter cysts with putty-like material between them. It was a typical example of a dead hydatid cyst which had been converted into an atheromatous mass. Hooklets were found in all the tumours.

Dr. ARNOLD W. W. LEA showed an Anencephalic Fœtus in which the whole of the medullary canal had remained open. The fœtus was a female weighing 2 lb. 12 oz., stillborn. The limbs and muscles were well developed. The face looked almost directly upwards, the neck being extremely short, as is usual in these cases. The vault of the skull was absent. The base was prominent and covered by a fine membrane adherent to it and continuous with the skin at the sides of the head. This membrane was also continued along the spinal column as far as the sacrum, and formed a band two and a half inches wide, extending from the angles of the ribs on each side. It was united laterally to the skin of the back. The vault of the skull ceased at the supra-orbital ridge; posterior to this, and attached to the base of the skull, were two solid masses apparently representing the cerebral hemispheres. On reflecting this membrane numerous nerves, cranial and spinal, were seen to pass from its under surface towards the foramina. The eyes and external ears were well formed. The base of the skull was very convex, and showed at each side of the basi-sphenoid a bony plate representing the wings of the sphenoid or the ex-occipitals. There were numerous foramina in the base of the skull. The laminæ and spinous processes of all the vertebræ were absent and no trace of the spinal cord could be detected. All the other organs of the fœtus were normal and well developed. This condition of the nerve centres appears to be the result of intra-uterine hydrocephalus occurring before the fourth week. As a consequence of this the ventricles and the central canal of the spinal cord become much dilated and ruptured, the fluid escaping. The cranial and spinal nerves are, however, developed from the nervous tissue remaining on the ventral aspect. The membrane then in these cases would consist of the pia mater and arachnoid, containing also a small amount of nervous tissue, and from this the nerves are developed. Cases of anencephalus are not very uncommon. It is, however, very rare to find the whole of the spinal canal remaining open, with consequent non-development of the laminæ and spinous processes of the vertebræ.—Dr. ARNOLD LEA also showed a Fœtus with Solitary Cystic Kidney, absence of Ureters, Imperforate Anus, Double Talipes Equino Varus, and Genu Recurvatum on the Right Side. The fœtus was a male, stillborn, weighing 3 lb. 12 oz. On dissection the heart and lungs were found to be normal. On opening the abdomen the most striking object was a large cystic organ occupying the right lumbar region and extending into the cavity of the pelvis, which it filled up on the right side. In position this structure corresponded to a kidney. There was, however, no ureter. On section numerous cysts, some very large, were seen scattered through it. There was no renal pelvis. Microscopically the solid part of the mass was mainly composed of fibrous tissue, with very numerous and large vessels and capillaries. The cysts were lined by cubical epithelium, the nuclei staining well and the cell substance being granular. Each cyst was surrounded by a capsule of fibrous tissue containing numerous round cells, some of which were pigmented. Hæmorrhage had occurred into some of the cysts. There were also groups of epithelial cells scattered through the structure, some of which resembled renal tubules. No glomeruli were observed. On the left side there was total absence of kidney and ureter. The urachus was wide, the bladder very small and empty, and the urethra patent. The suprarenals were large and well formed. The liver and spleen were normal. The stomach, small intestine, and greater part of the large intestine were normal. The sigmoid flexure passed down on the right side of the pelvis and ended by fusing with the base of the bladder, into which the end of the gut opened by a valvular opening admitting a probe. There was no anal depression. The vasa deferentia and testes were well developed, the latter being undescended. The origin of the cystic kidney of infants has been ascribed to intra-uterine inflammation occluding the papillæ. In this case, however, it appeared to be due to a developmental condition. The ureter and renal pelvis, which normally arise as

Digitized by Google

a protrusion from the lower end of the Woolfian duct, had failed to develop. The organ described above represents an embryonic kidney, development having been arrested at an early period. On the left side the portion of the Woolfian body which should develop into the kidney had entirely disappeared. The connexion of the allantois with the hind gut had remained patent and there had been no involution of the epiblast to form the anal end of the gut.

Dr. HUTTON showed the heart of a dog (an English setter ten years old) from the wall of the right ventricle of which a fibro-cystic tumour, an inch in diameter, grew. The wall of the right ventricle was thickened and the cavity dilated. The animal had been thin and feeble for about a year and had had three attacks of syncope in the last month and died in the third attack.

Dr. DIXON MANN and Dr. J. GRAY CLEGG described the post-mortem appearances of Two Cases of Poisoning by Arseniuretted Hydrogen and showed specimens. There were five cases in all, three terminating favourably. They occurred in a manufactory where for trade purposes it was necessary to dissolve a considerable quantity of zinc in hydrochloric acid. The hydrochloric acid used at the time of the poisoning was found afterwards to contain an excessive amount of arsenic as impurity to the extent of 0·309 per cent. of metallic arsenic. The zinc also contained arsenic in small amount. The symptoms were, briefly, pain in the back, vomiting, melæna, hæmoglobinuria, and jaundice. The post-mortem appearances were as follows: a broad, dark-blue line on the gums, ante-mortem clots in the heart and great vessels, œdema and congestion of the lungs, general bluish tinge of the omentum, hyperæmia of, and petechiæ in, the mucous membrane of the stomach and intestines, congestion of the spleen, slight enlargement of the liver, great swelling, and congestion of the kidneys. On section the substance was found to be dark-red and the pyramids showed blue-black patches in their central parts. The bladder was contracted, in one case empty, and in the other contained about a drachm of fluid tinged red, in which was found kidney epithelium, fatty casts, albumin, and a trace of bile pigment. In Case 1 arsenic was found to be present in the liver, kidneys, bile, urine, blood, and in the fluid from the pericardium and the pleuræ. In the liver only was the amount sufficient to enable a quantitative estimation to be made; it equalled 0·002 gramme As_2O_3 for the entire viscus. In Case 2 As was found in the kidneys, spleen, and liver, in which it equalled 0·0016 gramme As_2O_3. The microscopical preparations exhibited the following characters:—Liver: The cells were swollen and cloudy, but the nuclei stained; there was no appreciable bile staining and no deposit of iron. Spleen: There were extensive congestion and slight fatty changes with failure to stain in patches. Kidney: The glomeruli were swollen, epithelium of the tubules was swollen and cloudy, and the nuclei did not stain; the bloodvessels were markedly distended; and there were granular matter and blood in the tubules. Osmic acid preparations showed fatty granules in the cells of all the three organs.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Acute Perforative Appendicitis.—Exhibition of Cases and Specimens.

A MEETING of this society was held on May 1st, Mr. MAYO ROBSON, President, being in the chair.

Mr. MOYNIHAN read the notes of a case of Acute Perforative Appendicitis in which recovery followed abdominal section. A boy aged thirteen years had suffered for three and a half days from acute appendicitis, perforation occurring towards the end of the third day. The abdomen was opened by a median incision, and the peritoneal cavity, which was found to contain offensive pus, was thoroughly cleaned and drained. By a separate incision the abscess cavity over the appendix was opened and cleansed and drained. A prolonged convalescence eventuated in complete recovery. The chief points raised for discussion were the following: 1. The question of early operation in ordinary cases of appendicitis. Mr. Moynihan quoted Dr. Ryerson Fowler, who remarks: "As soon as the diagnosis of progressive appendicitis is assured the abdomen should be opened and the appendix removed." It was urged that early operation was attended by little or no risk and that its statistical results would be found to justify the procedure. 2. The administration of opium during the first forty-eight hours. This was strongly deprecated. The first twenty-four or forty-eight hours are those in which the symptoms are gradually asserting their claim to the surgeon's attention, and their relative value is wholly impaired by the effect of opium or morphia. 3. The advisability or otherwise of peritoneal lavage was discussed, and Mr. Moynihan gave it as his firmly established opinion that the method added very considerably to the dangers of the operation and in most cases was unnecessary. The peritoneum could be as thoroughly cleansed by careful sponging with tampons of iodoform gauze. Drainage by means of strips of gauze in place of, or in addition to, drainage by glass tube was advocated. 4. The importance of the removal of the appendix in all cases of abscess. It was pointed out that in not a few recorded cases a second attack of acute inflammation had occurred in an appendix not removed during operation and that in one case at least a fatal termination had resulted. It was suggested, as a guide to treatment, that some ready rule should be adopted, such as "if at the end of a certain well-defined period a case of appendicitis is either stationary or progressive operative procedures should, without any further delay, be adopted." It was mentioned that the American surgeons would constitute twenty-four hours as the duration of this period. This was, perhaps, a little early, but it emphasised the importance of early operative procedures—an importance that could hardly be too strongly insisted upon. — Mr. BROWN objected to the early use of opium because it concealed the danger. He thought washing of the peritoneum was of great value and that there were other more important factors in the production of shock.—Dr. CHURTON thought that a large number of these patients got well without operation and could recall many cases where a peritonitis had receded after rather rapid extension.—The PRESIDENT mentioned three cases in which he had operated with success. — Mr. LITTLEWOOD thought that perforation occurring during the first attack was much more serious than when occurring in later attacks. He did not believe it possible in many cases to absolutely cleanse the peritoneum, and thought it of importance to use boiled normal saline solution for intra-abdominal lavage rather than boric acid or plain water.—Dr. GRIFFITH drew attention to the anatomical arrangement of the peritoneum around the appendix and its bearing on the mode of bursting of an abscess within or without the peritoneal cavity.—Mr. MOYNIHAN replied.

The following cases, pathological specimens, &c., were shown:—

Mr. W. H. BROWN: (1) Patent Urachus closed by operation; (2) Enterectomy after Gangrene of Umbilical Hernia (specimen and patient); (3) Extensive Keloids; (4) Recurrent Fibroid after more than twenty removals; and (5) Talipes Equino-varus treated by Phelps's method.

Dr. CHADWICK: Case of Ataxic Paraplegia.

Dr. WARDROP GRIFFITH: (1) Case of Congenital Weakness of Inter-ossei Muscles; and (2) dissections to show the "Undefended Area" of the Cardiac Septum.

Dr. MANTLE: (1) Two adult patients with Muscular Atrophy; (2) Aneurysm of the Arch of the Aorta cured by rest and the application of an icebag; and (3) Cerebral and Spinal Hæmorrhage.

Dr. CHURTON: (1) Splenic Leucocythæmia; (2) Œdema without Albuminuria; and (3) Sarcoma of the Corpora Quadrigemina and Pineal Body.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.—The Treatment of Inoperable Cases of Cancer.

THE ninth meeting of this society was held on May 20th, Dr. ARGYLL ROBERTSON, President, being in the chair.

Mr. JOSEPH BELL showed a patient after a Gunshot Wound of the Forearm. The bullet from a rook rifle had passed obliquely through the lower end of the radius, shattering the bone. Portions of bone and of the bullet were removed. The patient made an excellent recovery. The movements at the wrist-joint were perfect. Roentgen photographs were exhibited exemplifying the condition of the radius after the wound had healed.

Dr. NORMAN WALKER showed a Powder for Photography

Digitized by Google

by Flash-light. The powder consisted of powdered magnesium and chlorate of potash on gun-cotton. It was efficacious and cheap, and by its use photographs could be taken irrespectively of the weather.

Dr. GILES also showed an Apparatus for Producing Flash-light.

Dr. GEORGE T. BEATSON read a paper on the Treatment of Inoperable Cases of Cancer. He remarked on the number of inoperable cases of cancer of the breast which he had seen in the practice of the Glasgow Cancer Hospital, and from which he had deduced a line of treatment which was opposed to the parasitic theory of cancer. The first case was that of a patient thirty-three years of age suffering from advanced cancer of the breast. After a confinement she noticed a lump in her breast. She sought advice at the Royal Infirmary, where the breast and axillary glands were removed. The wound healed well, but in three months the cicatrix broke down, discharged, and there was considerable hardness and thickening around the ulcer which formed. She was dismissed from treatment at the Royal Infirmary as in too advanced a stage of the disease for operation, the disease having returned in the whole scar. When first seen by Dr. Beatson there was a large cicatrix extending from the axilla forwards to the anterior mammary region. The whole cicatrix was a mass of recurrent carcinoma. She had the pale, cachectic appearance of a patient with advanced carcinoma. The diagnosis of cancer was confirmed by removing a portion of the tumour and examining it microscopically. The specimen was shown under the microscope and was of a typically cancerous nature. No operation was possible. The question arose, Could the disease be attacked in any other way? To discuss this Dr. Beatson glanced at the present knowledge of cancer. All were agreed that carcinoma was of the nature of an epithelial growth, that this growth spread locally and by infection through the lymphatic system, that there was no known means of arresting the growth, that cells known as cancer cells developed, that the younger the patient was the more rapid the fatal result, and that the best treatment was removal with the knife. All were agreed upon those points. All were not agreed on the local origin or not of the disease. Some thought it arose from local irritation, others from blood dyscrasia, and a third school held that in addition to the dyscrasia a local irritation was necessary. As regards "cancer bodies," some thought them specific of the disease and parasitic in nature and others described them as degenerated leucocytes or other cells. Dr. Beatson then went at considerable length into the influence of the ovaries on lactation, and the influence which removal of the ovaries had upon the mammary function in the lower animals. Was cancer of the mamma due, he asked, to an error in the function of the ovaries? When working at the Glasgow Cancer Hospital he tried the influence of thyroid extract in carcinoma of the breast. In the case described thyroid tabloids had been administered, but with no effect. As a possible method of benefiting the patient the removal of the ovaries and tubes was proposed. The operation and its effects being explained to the patient and her husband it was performed with their full consent. She made a good recovery from the operation. No local measures were taken with the breast save ordinary aseptic dressings. The thyroid tabloids were continued. A marked change in the cancer took place. The tumour became smaller and flatter and there was marked diminution in the surrounding thickening. The nodules in the axilla also diminished. The local improvement continued and four months afterwards the mammary tumour was noted to be greatly diminished in size and of a yellowish colour. All the tissues were more movable and the surrounding tissues more healthy. Six months after the operation all evidence of carcinoma had disappeared. She was now shown to the society in a healthy condition. A cicatrix extended from the mammary region to the axilla and there was absolutely no evidence of cancer either in the cicatrix or axillary glands. The second case was one of cancer of the breast in an advanced stage, which seemed to date from an injury to the breast. On admission the patient was noticed to be a cachectic, emaciated woman with a large tumour in the right breast adherent to the skin in the centre, but not fixed below. The nipple was retracted and there were large fixed glands in the axilla and extending in the neck as high as the lobe of the ear. There were no secondary deposits in other organs. No operative procedure was practicable. A microscopic section and cast of tumour were shown. She was admitted to the Cancer Hospital and during a month's residence the tumour spread rapidly. The tubes and ovaries were then removed. She made a good recovery from the operation. The breast tumour became less vascular. She felt better and the pain diminished, so that she was able to sleep at night without hypnotics. Thyroid tabloids were begun. Two months after operation, as the tumour and glands were diminishing, a nodule was removed for microscopic examination. The specimen, a carcinoma undergoing fatty degeneration, was shown under the microscope. The tumour did not diminish so rapidly as in the first case, but still the diminution was marked. Casts were shown exemplifying the condition before operation and some months afterwards. The third case was that of an unmarried woman with a large ulcerating tumour of the breast, but no glandular infiltration. A section of the tumour was examined and found to be cancerous, not tuberculous. As she had passed the menopause thyroid tabloids were given without removal of the ovaries. During the three months they had been taken no improvement was noticeable. The ulcerating tumour had spread. The thyroid tabloids had done no good, and it might be as well, Dr. Beatson thought, to remove the ovaries. He considered some pathological conditions in the ovaries the exciting cause of cancer of the mamma and female generative organs. He did not believe in the parasitic theory. He thought the ovaries in the female and the testicle in the male must be looked to for the cause of cancer. He thought that cancer cells could be ultimately shown to be germinal epithelial cells (ova). Epithelial cells became converted into germinal epithelial cells as found in the ovary, the conversion being due to some influence in the ovary. In the male the testicle seemed to have the same influence over proliferation as the ovary had in the female; this was exemplified in the horning of stags. He urged that removal of the ovary or testicle had an inhibiting influence on the proliferation of epithelial cells, and that removal of the ovaries in young nursing mothers had great influence on the development of carcinoma where local operation had failed. He did not urge the removal of the ovaries in early cases, but in *inoperable* cases. The views were problematical, but he urged the theory in the interests of those who were sufferers. The patients exemplifying the paper were shown.—Professor A. R. SIMPSON remarked that it was a well-known fact that disappearance of the ovarian function gave rise to the deposit of fat. He found from his own experience and from statistics that where both ovaries were removed patients died in an unusually large proportion from carcinoma. In Dr. Beatson's case the thyroid extract might have had some influence. The ovarian influence on the mamma seemed to be not only nervous but chemical as well.—Professor CHIENE thought that as a practical surgeon looking at the first case one would be justified in inoperable cases of carcinoma of the mamma in removing the ovaries and giving thyroid tabloids.—Mr. JOSEPH BELL said that the first case shown was one of the most remarkable he had ever seen in his life. The case was cured, and he thought all similar cases should have a like chance at the hands of surgeons. He had, however, seen a good many cases like No. 2, in which with the shrinkage of the whole woman a shrinkage in the tumour and glands took place.—Mr. STILES congratulated Dr. Beatson on the clear, modest, and cautious manner in which he had stated his case. The facts after seeing the first case and the specimen could not be disputed. He agreed in not regarding cancer bodies as parasites. In slowly growing tumours of the mamma the death-rate of the cells was almost as great as the birth-rate, and in rapidly growing tumours the opposite was the condition. He thought that removal of the ovaries might check the birth-rate. In the first case the patient was a young woman, and the ovaries had great influence on the mammary gland, and removal checked the birth-rate of the cells. He did not think that removal of the testicle could have much influence on the growth of cancer.—Dr. WALKER, Dr. JAMES RITCHIE, and Dr. LUNDIE took part in the discussion.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Some Modifications of Midwifery Forceps.—Criminal Abortion in the Punjab.—Technique of the Dilatation of the Perineum in Labour.—Teratogenesis: an Inquiry into the Causes of Monstrosities (Part II.: Theories of the Past: Physical Causes).

A MEETING of this society was held on May 13th,

Digitized by Google

Professor SIMPSON, in the absence of the President, being in the chair.

Surgeon-Captain CHARLES H. BEDFORD sent some Abortifacients used in India for exhibition: the roots and twigs of Plumbago rosea, "Lal Chitra," which externally and internally act as an irritant, and are used to procure abortion (rarely for homicidal poisoning); the Fruit of Terminalia bellirica, which acts as a narcotico-irritant poison; Markingnuts; drupes of Semecarpus anacardium; "Bhilawa" juice, which is applied to the cervix-uteri as an abortifacient; and also abortion sticks, "battis," from the Punjab; the sticks are dressed with cotton-wool which is smeared with an irritant paste of nutmeg, arsenic, juice of Calotropis gigantea, jequirity seeds, carbonate of sodium, aloes, &c., and then passed into the cervix uteri.

Dr. J. W. BALLANTYNE showed an Anencephalic Fœtus; there had been scarcely any liquor amnii present.

Dr. G. OWEN C. MACKNESS read a paper on Some Modifications of Midwifery Forceps. He said that the handles in an ordinary pair of forceps served as a means of introduction of the blades and also afforded a grip while traction was being effected. In the axis-traction forceps the handles served, as before, for the introduction of the blades, and they also acted as indicators for the axis of traction. These handles were not now used for traction, and they therefore seemed unnecessarily long and heavy for the purposes which they required to fulfil. He had had forceps constructed where these handles were reduced from six to three inches; he had used them in many cases and found that they were more easily applied with the patient in a confined space or where there was no skilled assistance to get and maintain her in a suitable position. They were lighter and less cumbersome, and in occipito-posterior cases during rotation the handles were much less liable to jam against the thigh. The centre of gravity of the forceps was brought nearer to the blades and therefore nearer to the point where the power was applied. He had also altered the plate attached to the traction handle for the reception of the buttons on the ends of the traction rods. By cutting away the bridge which separated the apertures for the insertion of the buttons more space was allowed for their rapid removal, and the difficulty in their disconnexion, when the blades were widely separated by an unusually large head, was thus overcome. There was no binding connexion between the traction rods. These were made separable from the blades, but the end of the rod and the slit in the blade for its reception were so formed that it was impossible for them to slip out when the forceps were in use. The fixation screw was made very strong and was placed at the end of the application handles. The instrument was made entirely of metal, and the handles were roughened to prevent slipping during their use.—Professor SIMPSON preferred the full length for the application handle so as to effect more easily the manipulation of the blades on the head and their locking afterwards. He was favourable to the placing of the fixation screw at the extremity of the handles and commended the forceps as a step towards simplicity.—Dr. FORDYCE and Dr. MCVAIL took part in the discussion.

Surgeon-Captain CHARLES H. BEDFORD sent a paper on Criminal Abortion in the Punjab, which was read by Dr. J. W. BALLANTYNE. The cases occurred during twelve months previously to November, 1894; the facts detailed were derived from the official reports of the local medical officers and police, these including the post-mortem examinations and the symptoms noted during the treatment of the cases. Surgeon-Captain Bedford also included his chemical and special examination of the articles and viscera sent to him. Twenty-six cases were referred to him during the year indicated and death had occurred in all. These probably only represented a very small fraction of the fatal cases of criminal abortion occurring in the Punjab and an infinitely smaller proportion of the non-fatal cases. They occured mostly among the unmarried; widows debarred by the social customs of the country from re-marrying were the principal offenders. The production of abortion was principally in the hands of native nurses and midwives and male native quacks, who used methods in use in India for probably hundreds of years. The administration of substances by the mouth for the purpose in view was less common than by local means. The paper explained the Indian law on the subject and compared it with the English. The general means employed in India were emetics, purgatives, irritants, ecbolics, &c. The local means generally consisted in the introduction into the os of some medicated twig or bougie or by the application of irritant substances in the form of a paste to the os uteri either by the finger or on cotton-wool. Death might occur from sepsis after the abortion had been induced or by peritonitis from injury to, or even perforation of, the uterus. The substances employed as abortifacients in these cases were various: nutmeg and arsenic were employed in four cases; opium in two cases; crude carbonate of sodium, black pepper, mercury, croton and aloes, alum and saffron, each one; and portions of twigs or "battis" were found in four cases. These were pieces of wood a few inches in length, dressed at one extremity with cotton-wool (just as a uterine sound would be), and this end was smeared over with a paste of pounded nutmeg or with arsenic. Other substances were used for this purpose—jequirity, madar juice, croton seeds, quicklime, &c. At other times these substances were applied on pledgets of cotton-wool and placed by the finger on the os uteri and left there. Occasionally the "batti" was extracted after a time, more cotton-wool applied, re-charged and again inserted; this was repeated until the os was dilated, when the membranes were ruptured. Or three or four "battis" might be inserted alongside one another. Out of the twenty-four cases four occurred at the third month, eight at the fourth, five at the fifth, and one at the sixth month. Post-mortem examination revealed in one case a portion of the twig penetrating the isthmus uteri, in another the cotton-wool was found in a wound of the uterine wall, in another a twig was found *in utero*, and a pledget of wool smeared with arsenic was found in the cavity of the cervix in another. Septicæmia and peritonitis were the causes of death in ten cases, two died from opium poisoning and one from aconite and opium. Abortion had occurred in twenty out of the twenty-six cases before death.

Dr. G. COROMOLAS (Calamata, Greece) sent a paper on the Technique of the Dilatation of the Perineum in Labour, communicated by Dr. J. W. BALLANTYNE. The woman being placed in bed on her back or left side with the legs as in natural labour, the vagina and external parts were thoroughly washed and rendered aseptic. The hands of the accoucheur were also carefully prepared and smeared with an ointment of vaseline with 6 per cent. of cocaine and antipyrin. The perineum, vagina, and os uteri were also anointed with this. The accoucheur then passed four fingers of one hand within the vaginal orifice and made some semilunar movements, first at one side and then at the other, so as to dilate the perineum. After having made three or four powerful movements he introduced the fingers of the other hand and repeated the same procedure. When the requisite degree of dilatation was achieved he then passed the fingers fully into the vagina until the index, middle, and ring fingers touched the os uteri; the same movements were again carried out, the perineum being then pushed outwards by the palmar surface of the hand. This was persevered with until he felt the presenting part pressing upon the dorsal surface of the fingers. By this proceeding the perineum and labia were guarded against rupture and labour was hastened. The use of the analgesic ointment allowed of delivery without severe pain.

Dr. J. W. BALLANTYNE read a paper on Teratogenesis: an Inquiry into the Causes of Monstrosities (Part 2: Theories of the Past: Physical Causes). The early Greek philosophers looked for purely physical causes of monstrosities; these they found in disturbances of the natural phenomena of reproduction. Their views upon reproduction varied; some regarded the semen as the sole or principal factor and the woman was only a temporary abode for the fœtus. Others were of opinion that the menses supplied the material in generation and that the semen was of comparatively little importance; others, again, believed that both were necessary. The menstrual blood seemed sometimes to have been called the female semen, and the sex of the fœtus was supposed to be due to the greater strength of one or other seed. Another notion was that boys were generated in the right testicle and girls in the left, or the sex depended on the side of the uterus which received the deposition of the semen. Another belief which influenced their views of monstrosities was the supposed fertility of animals of different kinds with one another or even with man. Monstrosities were considered by some to be due to abundance or defects of the semen, from slowness of movement, from division of it into several parts, or from aberration of movement. The menses were believed by some to play an important part in the generation of monsters. This was largely due to Hebrew legislation regarding coitus during or immediately after the flow, as an infant conceived at that time was regarded as certain to be either an epileptic, a

Digitized by Google

cretin, a drunkard, or insane. In classic mythology Vulcan was begotten by Jupiter when Juno was menstruating. Pliny and writers in the Middle Ages attributed maleficent powers to the menses as regards vegetables, metals, glass, trees, and even animals, so it was not to be wondered at that writers found in it one of the causes of deformed births. The theory that monstrosities were due to human and animal intercourse held some ground even down to the Middle Ages, so that if a woman gave birth to a fœtus in any way resembling an animal she ran very considerable risk of being burnt alive with her offspring and the animal supposed to be implicated. Such a fate befel a woman in Copenhagen in 1683 as a result of the birth of an anencephalic fœtus. Suspicion also fell upon an animal that brought forth a fœtus in any way resembling the human type, as a hydrocephalic foal or calf, and Albertus Magnus saved a shepherd's life by announcing that such an event was due to stellar influence. It was not till the beginning of the eighteenth century that a strong protest was made against the belief in the hybridity theory of teratogenesis.

Reviews and Notices of Books.

Occasional Papers on Medical Subjects, 1855–1896. By W. HOWSHIP DICKINSON, M.D. Cantab., F.R.C.P. Lond., Hon. Fellow of Caius College, Cambridge; Consulting Physician to St. George's Hospital and to the Hospital for Sick Children, Great Ormond-street; President of the Royal Medical and Chirurgical Society; Corresponding Member of the Academy of Medicine of New York. London, New York, and Bombay: Longmans, Green and Co. 1896.

THERE are two main points from which improvements in medicine in this century start and to which nearly all that distinguishes modern medicine so creditably can be traced; the first is the work of Richard Bright on the kidney, dating back to 1827, and the other the work of Pasteur adopted and applied and developed in this country by Lister. From these two pieces of work respectively date the chief researches of physicians and surgeons which have revolutionised our conception of the structural basis of disease and of its causes. Amongst English physicians who have worked hard and appreciatively on the lines of Bright is the author of the work which we have much pleasure in commending to our readers—not the less so since our own pages have been the medium through which the profession made the acquaintance of not a few of his papers. It is characteristic of Dr. Dickinson not only to have the keenest sense of what constitutes the clinical evidence of disease, with a refined eye for its minutest features, but to have the industry to follow his fatal cases to the post-mortem room and to exact from them the fullest information, accepting most candidly whatever they have to tell either in support of his previous diagnosis or otherwise. The Occasional Papers are the result of this double study of disease at the bedside and post mortem. Two other qualities of the author go to make the papers, already full of instruction, also very readable. The first is—shall we say?—a slightly pugnacious mental element giving enjoyment by the demolition of a theory which does not seem to him tenable, whether it be the embolic theory of chorea or the usually accepted theory of the so-called presystolic murmur. The second is a singularly clear and good style of writing, founded on the best English classics, a style which has placed Dr. Dickinson's works in the front of our medical literature.

The papers cover a large number of subjects which are of interest to all practitioners. The whole constitute a volume of 247 pages, to which there is a useful index. We need not enumerate all the papers—eighteen in number—but the mention of the following will suffice to show that they touch at once the deepest questions in pathology and such as are of daily interest in medical practice on the Action of Digitalis on the Uterus; Three Cases of Angina Pectoris depending upon Occlusion of the Mouths of the Coronary Arteries; on the Enlargement of the Viscera which occurs in Rickets; on the Pathology of Chorea; on Chorea with reference to its Supposed Origin in Embolism; on Cirrhosis of the Liver in Childhood; on Hereditary Albuminuria; on the Morbid Effects of Alcohol as shown in Persons who trade in Liquor; on Albuminuric Ulceration of the Bowels; on the Cardio-vascular Changes of Renal Disease, with some Observations on the Larger Arteries; on the Practice of Medicine at St. George's Hospital Forty Years Ago; on the Presystolic Murmur falsely so-called; and on Alkalies in Rheumatism. The last paper is a very important deliverance on the respective use of alkalies and salicylates in acute rheumatism based on forty years' experience. It seems to show conclusively that the alkalies used freely, as described, protect the heart as no other treatment does, though Dr. Dickinson associates with them the salicylates. The paper on Alcohol is a grave indictment against the free use of that substance. The article on Medical Practice Forty Years Ago shows vividly how recently the practice of medicine, even in the hands of such philosophers as Dr. Thomas Young, consisted of methods which we should be glad to forget.

Journal of Anatomy and Physiology, Normal and Pathological, Human and Comparative. Conducted by Sir GEORGE M. HUMPHRY, Sir WM. TURNER, and Professor J. MCKENDRICK. Vol. XXX. Part 3. April, 1896. London: Charles Griffin and Co. Price 6*s*.

THE present part contains sixteen articles, which are as follows: 1. Arthur Robinson, M.D.: Formation and Structure of the Optic Nerve and its relation to the Optic Stalk, with one plate, an article which we notice on another page. 2. E. W. Carlier, M.D.: On the Pancreas of the Hedgehog during Hybernation, a gland which he found to, his surprise to be in a moderately active state. He describes the microscopical characters of the gland at considerable length. 3. Keith Campbell, M.B.: An Accessory Segment in the Pulmonary Valve, with an engraving. 4. Studies in the Peritoneum, its Arrangement in Animals, by Byron Robinson, M.D., of Chicago. In this paper the author gives the results of his examination of a considerable number of animals, such as the cat, dog, ferret, polecat, badger, otter, pig, and rabbit. 5. J. H. Sequeira, M.D.: A Case of Ectopia Vesicæ, with Patent Vitelline Duct. 6. Edred M. Corner, B.Sc.: Some Structures in the Elbow-joint. 7. The same author on the Temporal Fossa. In both papers a very careful description is given of the structures forming the joint. 8. Mr. Corner also describes the processes of the Occipital and Mastoid Regions of the Skull, especially commenting on the processes named in some works of anatomy the "paramastoid" and "paroccipital," both of which he considers to have been frequently present. 9. E. Barclay Smith, M.D.: On the Astragalo-calcaneo-navicular Joint, giving a very exact account of the bones and the ligaments of this joint. 10. David Hepburn, M.D.: Observations on the External Appearance and Visceral Anatomy of the Grey Seal (Halichoerus Grypus.) 11. Johnson Symington, M.D., Professor of Anatomy at Queen's College, Belfast: On the Homology of the Dumb-bell-shaped Bone in the Ornithorhynchus, in which the different views are discussed of this peculiar bone. 12. What is Sibson's Muscle? (Scalenus Pleuralis) by Professer Edward Fawcett, M.B. 13. Hereditary Polydactylism, by Gregg Wilson, M.A., in which the disposition of the bones of the hand is given by the Roentgen ray process. In addition to the above items there are a Report on Recent Teratological Literature by B. C. A. Windle, M.D., and the Proceedings of the Anatomical Society of Great Britain and Ireland.

Domestic and Sanitary Drainage and Plumbing. By WILLIAM R. MAGUIRE, Associate of the Institution of Civil Engineers of Ireland; Registered Teacher of Plumbing, City and Guilds of London Institute; and Registered Master Plumber, Worshipful Plumbers' Company, London, &c. Second Edition. London: Kegan Paul, Trench, Trübner and Co., Limited. 1896. Price 12*s.*

THE second edition of a book, unless it shows some very marked improvement over the first, does not usually call for more than a passing notice, but the subject with which this volume deals is so very important to the health of the public that a brief *résumé* of its contents may not be out of place. It is not necessary at the present day to dwell upon the connexior between plumbing and health, or rather bad plumbing and bad health, but with regard to this subject there is reason to believe that the general public do not show that amount of interest which for their own welfare they should do. The book consists of a series of lectures, delivered at the Central Technical Institute at South Kensington under the auspices of the City and Guilds of London Institute for the Advancement of Technical Education acting in conjunction with the Worshipful Company of Plumbers, which were primarily delivered for plumbers and engineers, but all who live in a dwelling of any description will peruse the book with advantage. The author fully appreciates the need of workmen thoroughly understanding the scientific principles upon which their work is based. In one of the early chapters he says:—

"Popular education in physics ..... has been so neglected that very few otherwise well-educated people are prepared to explain, or even to understand, the causes of the most simple practical phenomena occurring daily within their observation ..... the world is looking for plumbers and for technical teachers of plumbing who make it their aim to know their business thoroughly. Knowledge of the forces of nature is more essential for plumbers than for the artisans of many other trades."

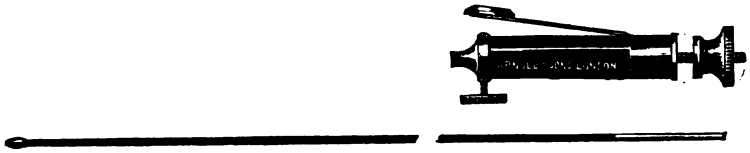
These words give some idea of the position the lecturer takes up and the exposition of energy and matter which follows is succinct but practical. Hydrostatics, hydraulics, and aerometry are treated in an elementary but thoroughly practical manner, and heat receives considerable attention. Sewage Disposal, Sewerage and Drainage, and Water Supply from the plumber's point of view are the heads of chapters which show the writer to be a practical man. The chapter on Sanitary Appliances is a valuable one inasmuch as without dogmatising on the advantages of any one particular maker's wares it shows the construction of the various types of apparatus—in many instances giving sectional drawings clearly showing their action—and describes in detail the qualities which all sanitary appliances should possess. Some thirty pages are devoted to the important question of hot water supply, and the cause and prevention of domestic boiler explosions are lucidly discussed. The book, which is well illustrated, should be read not only by plumbers and those engaged in the building of houses but also by every owner or occupier of a house who wishes to understand some of those details which govern the healthy construction of his habitation.

New Inventions.

SOME NEW RHINOLOGICAL AND OTOLOGICAL APPLIANCES.

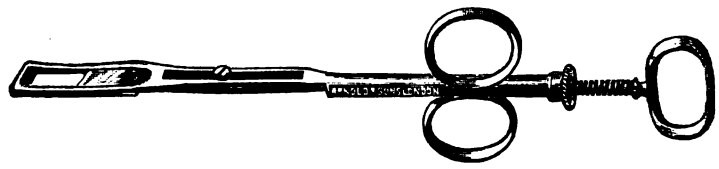
I DESIRE to draw attention to a few appliances which will be found of use in the treatment of certain nose and ear affections. My former rheophore, made of gum elastic with steel wire and silver knob, had the disadvantage that it could not be passed into the Eustachian tube. The one I now show (Fig. 1) can be readily passed through the Eustachian catheter, and is then easily connected with the lever contact handle by the small screw shown in the illustration. It has been perfectly made for me by Messrs. Arnold and Sons.

FIG. 1.—RHEOPHORE.



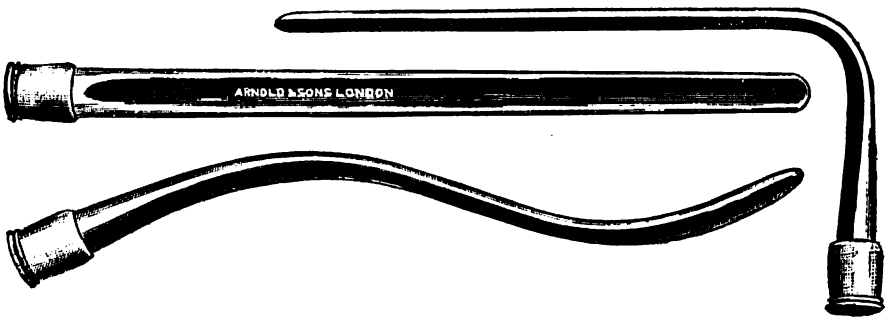
The turbinotome (Fig. 2) will be found useful for removal of portions of the inferior and middle turbinals when such a procedure is required. There is a strong spring in the handle which increases considerably the driving force of the blade, the cutting edge of which is crescentic in shape to prevent jamming. It also is made to my design by Messrs. Arnold and Sons.

FIG. 2.—TURBINOTOME.



The bougies which are shown in Fig. 3 are modifications of Mackenzie's and Stoker's. They have the advantage of being perfectly pliable, can be bent into, and retained at, any angle, or even twisted on their own axis. This has been achieved, at my suggestion, by Messrs. Arnold and Sons, who have made these bougies for me, six sizes being contained in a small flat box. They are most useful both for diagnostic purposes and as nasal dilators. The pliability is obtained by a thin layer of lead, which is covered by gum elastic.

FIG. 3.—BOUGIES.



Harley-street, W. H. MACNAUGHTON-JONES.

THE LANCET.

LONDON: SATURDAY, MAY 30, 1896.

THE General Medical Council will meet on Tuesday next at two o'clock in its new chamber, which is not quite so ample as the old one, but it is well ventilated and lighted and promises also a decided improvement in regard to acoustic qualities. The Council will find itself without a President, for the term for which Sir RICHARD QUAIN was appointed President expired on Tuesday, the 26th inst. He still continues to be, as he has been since the year 1863, a representative of the Crown, with an almost unparalleled experience of the proceedings and the business of the Council. It is not improbable that the Council will be glad to have Sir RICHARD QUAIN in the chair as long as he is willing to occupy it. Though well entitled to a less arduous seat, the Council may do worse for the present than ask him to retain the office which he has filled so well. There will be two new members in the Council well qualified to give weight to its deliberations—the one Sir WILLIAM ROBERTS, in the place of Dr. WILKS, as representative of the University of London; the other, Dr. W. THOMSON, direct representative for Ireland, in place of the late Dr. KIDD.

It is difficult in the absence of the programme of business to forecast with accuracy the subjects to which the Council will devote most of its time. But even so, it is not impossible to anticipate some of the chief questions with which it will have to deal. As on most occasions, these arise out of previous proceedings of the Council in relegating to the Executive Committee or some of the special committees of the Council subjects for consideration and report. A resolution of the Council in November, proposed by Dr. GLOVER, required the Executive Committee to consider the subject of the disciplinary functions of the qualifying medical authorities and of the General Medical Council, and to report to the Council at its approaching meeting on the best means of further defining and confirming these functions and bringing them into harmonious and efficient coöperation. The saving in time and funds to the General Medical Council will be immense if the qualifying authorities will do their duty, and the profession will be disappointed if some practical suggestions are not forthcoming for making all bodies which confer diplomas or degrees primarily responsible for the professional conduct of their diplomates. The Executive Committee has already gathered a large amount of information on the subject and has relegated to a sub-committee the power to take legal advice on the question, with the view of extending, where necessary, disciplinary powers to the medical authorities. This may require an application to Government for legislation, but the Council would be well supported by the profession in any such application, and it would be the more likely to be heard inasmuch as it has used its own penal powers with almost excessive moderation and been slow to ask for more. A subject of great interest will be raised by a motion of which Mr. TEALE gave notice six months ago regarding "the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it." The full text of his resolution will be found in another column. No one who knows Mr. TEALE will think that he would be a party to any lowering of the standard of medical education or efficiency, but the examining system is assuming prodigious proportions which do not necessarily involve any increased efficiency in those who pass. Mr. TEALE draws a distinction between what a man should know and what he should "know about," and we may be certain that if he would restrict the area of examination he would not restrict its thoroughness.

The General Medical Council will have to revert to a consideration of its duties in regard to the Apothecaries' Hall of Ireland under circumstances of the most delicate character. By its past action—taken certainly in good faith and for very weighty reasons—it has involved the Privy Council in a question foreign to its tastes and in which it is entirely inexperienced. The Privy Council has suggested to the General Medical Council through its legal representatives that the latter body might see its way to appoint examiners, not only surgical but medical. The question is not an easy one and in all probability there will be considerable discussion thereon. Much, too, may depend on the way in which the Apothecaries' Hall prepares its new application. In any case the General Medical Council is associated with the Privy Council for the first time in its history, and it will be interesting to see how the two bodies coöperate for the settlement of a question — not great, perhaps, but delicate — in the politics of a profession which has hitherto been so well governed from within as to make the interference of the Privy Council unnecessary. No one who watched the proceedings of the Privy Council could fail to see that their lordships were reluctant to interfere and were in no way anxious to violate the domestic government of the profession.

The General Medical Council has so clearly and fully expressed its views on legislation for regulating the practice of midwives or midwifery-nurses that it may not feel itself called upon at the present meeting to spend more time over it. But a report may be expected from a committee on midwifery diplomas—that is, on documents issued by the Rotunda Lying-in Hospital and the Coombe Lying-in Hospital purporting to be diplomas and to be recognised by the Local Government Board as qualifications in midwifery. This assumption of the right of "qualifying in midwifery" on the strength of six months' training, and in the face of the Act of 1886, by hospital officials, unrecognised in the schedule of the Medical Acts is a very serious matter on which the Council should be very explicit. The Education Committee will have to report on the Recommendation of the Council on the subject of Practical Teaching in midwifery raised by a petition from the council of the British Medical Association. This recommendation has often been discussed, and is regarded by many critics as being altogether inadequate and unworthy of the Council. If it emerges again unscathed from the Education Committee it will be a greater wonder than ever. A revised list of

Digitized by Google

preliminary examinations held in the United Kingdom will be proposed by the Education Committee, and the Examination Committee will report on the consolidation of the recommendations of the Council respecting examinations in relation to the amendments adopted at the last meeting of the Council. The Report of the Pharmacopœia Committee may be expected to announce the progress of the preparations for a new edition of the Pharmacopœia, conceived in a more imperial spirit than its predecessors and with a little more adaptation to medical uses, but not otherwise greatly altered.

These are the subjects to a consideration of which the Council is committed, and which may well occupy the time which it ordinarily spends over its summer meetings. Besides these it may be assumed that there are various charges of professional misconduct to be investigated which will occupy a day or two of the time of the Council. It was reported in the newspapers that the Alliance of Medical Aid Associations had resolved to appeal to the General Medical Council as complainants against their medical officers. It remains to be seen whether bodies which in the opinion of the profession have done so much to degrade the public estimate of medical service will have the courage to seek redress from the General Medical Council. It is scarcely likely that the Council which resisted the appeal of the profession will be moved by that of the associations. It may nevertheless have the opportunity through its President of saying a word in season to the representatives of the associations on their duties to the medical profession.

PROHIBITIVE legislation with regard to liquor is one of the most difficult problems in the whole range of practical politics. The question is indeed so difficult and so much embittered by controversy that there is the more need for spreading knowledge regarding it and for endeavouring to the utmost of our ability to profit by the experience which is being gradually accumulated in various parts of the world regarding the best means of grappling with what is universally admitted to be a great evil. Temperance reformers are not always well informed and are too apt to assume that their pet panacea would manifestly accomplish all the wished-for objects and soon afford us the spectacle of a transformed world. More cautious thinkers admit the evil but question the efficacy of most of the suggested remedies and are shy of committing themselves to schemes which might remove or palliate some of the evils of the existing system at the expense of calling into existence perhaps even greater evils. The question is eminently one for calm and judicial consideration, and in no other field of reform is it more imperative that we should profit to the utmost of our power by the successes or failures of other nations and countries. Mr. LECKY points out very justly that "the increasing sensitiveness of public opinion to questions of drink is very far from implying that the evil itself is an increasing one. There is strong reason to believe that the exact opposite is the case. A hundred years ago drunkenness was rather the rule than the exception among the upper classes; but with changed habits, and under the stress of public opinion, it has in this section of society almost disappeared. There are, no doubt, still some dissipated circles where it may be found, and most physicians can point to cases among the upper classes of secret drinking, which is, perhaps, usually of the nature of a disease; yet it is probable that many of my readers may have moved widely and constantly through good society, mingling with men of various tastes, habits, and professions, without having ever seen at a dinner-table a case of positive drunkenness." We entirely endorse this view, but we are not confident that any similar change for the better has taken place in the lower ranks of society. Mr. LECKY believes that there has, and we can only hope that it is so. We will not follow the distinguished historian through his very just but somewhat obvious remarks that much drunkenness is due to miserable homes, bad cookery, impure or deficient water-supply, unhealthy conditions of labour, adulterations, want of innocent and wholesome amusements, and so on. On these points much might be said, but the conclusions which the facts suggest are, on the whole, self-evident. We prefer at present to devote the space at our disposal to an endeavour to sum up the valuable facts detailed by Mr. LECKY regarding the various prohibitive or repressive measures attempted in various countries in relation to the liquor traffic.

Scotland led the way in these islands by a Sunday closing measure passed in 1854, Ireland followed with a similar measure in 1877, and Wales in 1882. Similar legislation has already been adopted in nearly all the colonies. It is in the United States, however, that the most determined efforts have been made to grapple with the drink-evil. Prohibition was adopted in the State of Maine in 1851, extended in its operations in 1877, and made part of the State Constitution in 1884. Other States have followed this example, but the fate of prohibition in America has been a curious and instructive one. "At the close of 1894 there were seven States in which the manufacture and sale of spirituous and malt beverages were forbidden, though the citizens of those States may obtain them for their own private use from other States. Nine or ten other States had tried prohibition and abandoned it, and they include some of the most important and populous States of the Union, amongst others New York, Massachusetts, Ohio, Illinois, and Rhode Island." It would appear that prohibition has achieved a certain amount of success in thinly populated territories—although even in these it has been the occasion of extensive smuggling and illegality—but that it has been almost a complete failure among the large centres of population. More success would seem to have attended the system of making the licences expensive and legalising some degree of local option. Canada has followed somewhat similar lines of policy. The Scott Act of 1878 provided that "on the petition of a quarter of the electors of any town or city a direct vote should be taken on the question whether it should be placed under the provisions of the Act. If a bare majority of the voters desired it, the question was decided for three years. In that case all public-house licences lapsed at the end of the year without compensation to the owners, and the ordinary manufacture and sale of intoxicating liquors as a beverage was absolutely prohibited." This system proved a failure in practice, and as a general rule the

Digitized by Google

former licensing system has been resumed. In New Zealand a somewhat stringent system of local option is in force. In most of the other Australasian colonies "the principle of local option, limiting the number of licences in a given district, generally prevails, though with considerable variations of detail and with considerable degrees of stringency." In Scandinavian countries the well-known Gothenburg system has been extensively adopted. By this scheme the sale of spirits and wines is granted as a monopoly to a company composed of leading citizens, who bind themselves by charter not to derive any profit from the sale of these liquors, the company being also empowered to sell malt liquors, coffee, tea, soda- and seltzer-water, cigars, and food at the ordinary scale of profits. The results of the general adoption of the Gothenburg system in Sweden and Norway have been very striking. Intemperance has been immensely reduced, "the consumption of spirits has shrunk to a mere fraction of the former amount," beer has largely replaced spirits, to the great benefit of the community. In Switzerland, where drunkenness had assumed alarming proportions, drastic measures were adopted in the year 1887. A law was passed prohibiting private distilling, and the State became the one wholesale spirit merchant. It was enacted that one-fourth of the spirits sold should be distilled in Switzerland, that the profits of the monopoly should be distributed among the different cantons, and that at least one-tenth of the surplus revenue should be employed in some way calculated to counteract the evil effects of alcohol. Considerable success has attended this measure and the consumption of spirits has been reduced 20 to 25 per cent.

We shall leave the above facts to speak for themselves. They seem to point emphatically to two or three conclusions. They show that the drink-evil is a real one, and that many countries have been compelled to face it. They show that the policy of prohibition has been, on the whole, a decided failure. They show that great success has attended prudent measures of regulation and repression. The logical deduction would seem to be that we must in this country prepare ourselves for some developments of legislation with regard to liquor, and that while we should view with great suspicion all extreme, tyrannical, and confiscatory schemes, we should lend a patient and attentive hearing to any moderate and well-considered measure of reform.

No words of greater weight than those we recently quoted from Mr. LECKY'S work on "Democracy and Liberty"[1] are needed to advocate the right of medical men to a place in the House of Lords as a reward for the services which they render to their country; but there is another argument which may be put forth, not resting on the claim of medical men to be rewarded in common with members of other professions for their services by admission to the Peerage, but founded on the advantages which might accrue to the country if the medical profession were represented in the Upper Chamber. Surely it is an anomaly that, while the highest legislative body in the land numbers among its members men learned in the law and in the making of laws, there should be none who possess by special study a knowledge of a subject with which an important part of those laws deal, the subject of public health. We say "an important part" advisedly, for on the health of a nation depends in a great measure its wealth, and the wealth of a nation, all other things being equal, is a criterion of its power. Not only is it an anomaly, therefore, but to a country like England a reproach, that among those who possess the right to veto measures brought in by the Lower House dealing with matters on which the whole stability of the country must ultimately depend there should be no member who can boast of a practical knowledge of medicine, knowledge upon which the great work of sanitary reform—"the noblest achievement of our age," as Mr. LECKY says—is based.

In days gone by, when little or no attention was given by our legislators to sanitation, there may have been some excuse, although no justification, for the omission of medical men from the House of Lords; but in the present day, when the importance of laws relating to public health is becoming more and more recognised, the filling of such a gap would be in keeping with the progress of the age and materially assist the work of sanitary reform. Endeavours have been made to educate the people in the laws of hygiene, and their representatives in the Commons can be trusted to a certain extent to see that the national health is looked after. But the House of Lords is not an elected body, and, therefore, whatever may be the wishes of the people they have no power to place representatives in the Upper House. To rightly deal with matters on which the health of the public depends involves a knowledge only to be gained by the study of medicine, and though it is true that there are in the House of Lords men of high scientific attainments who, by reason of their special knowledge, are able to take a scientific view of health questions, such details as can only be rightly understood by a medical man have practically to be left to the care of those who by necessity must have only a theoretical knowledge of such matters. In certain cases expert advice is absolutely necessary, and special committees are appointed to deal with special questions before they are dealt with by the Legislature, but how much time and how much expense might be saved to the nation if the legislative body in the first instance were partly composed of those whose training gave them the right to deal with the subject practically? A distinguished member of the House of Lords has himself seen the desirability of the creation of medical peers. Lord REAY, commenting at a recent dinner on the absence of the medical profession from the Upper Chamber, said: "We should be all the better for expert advice in the House of Lords," and no truer remark could have been made: the country would indeed be undoubtedly "all the better" if the roll of the peerage contained the names of men learned in medicine as well as of men learned in law.

This being so it would have afforded us the greatest satisfaction and pleasure—and in saying this we can claim to represent the feeling of the whole of the medical profession—if the recent list of peers among the Birthday Honours had included the name of one whose services to the nation and to humanity, in the introduction

[1] THE LANCET, May 2nd, 1896.

Digitized by Google

of antiseptic surgery, have received universal recognition. Such services are indeed beyond reward, but the admission of the President of the Royal Society, the recipient of numerous honorary distinctions from universities and learned societies, both English and foreign, would add lustre to the peerage. It is from amongst such men that the Second Estate of the Realm should be reinforced if, as it should, it is to contain the real nobility of our land. It is equally a matter of surprise and regret that this occasion should have passed without other leaders in medicine, science, and literature receiving that recognition from the Head of the State which is so freely accorded to the politician.

Annotations.

"Ne quid nimis."

THE CHURCH ANTI-VIVISECTION LEAGUE AND HOSPITAL SUNDAY.

WE have received the following, which we print exactly as it stands:—

158, Lancaster-road, W., May 7th, 1896.

DEAR SIR,—Our Committee feels that the approach of Hospital Sunday makes it desirable to bring before you the great influence the Clergy have in their power to exert towards the diminution of Vivisection by stipulating as a condition of assisting the Mansion House Fund by their offertories that they shall only be given to those hospitals which have no vivisectional laboratories attached to them. The Committee is aware that the Mansion House Committee may very likely refuse compliance with this condition at first, but if made by many of the Clergy it must ere long succumb to the force of public opinion, and the Clergy will find this change heartily welcomed by many members of their congregations who now scruple to contribute on Hospital Sunday. So long as the Clergy contribute to the support of those Hospitals which have laboratories attached to them they are directly supporting and subsidising vivisection, and they are alienating from the Church an increasing number of their people. Great and solemn, therefore, is the responsibility of the Metropolitan Clergy in this matter. If there are any Clergy who doubt the urgency of the case the Committee of the Church Antivivisection League will be glad to supply them with full information and proof of the assertions contained in this letter.

Signed by order of the Executive Committee,
E. A. SABEL, Hon. Assist. Secretary.

We have no idea who the members of the Church Anti-vivisection League may be, whether laymen or clerics, or what the standing of the latter may be, and we are not now going to argue the question from the scientific point, but in view of the statement that an increasing number of people are being alienated from the Church by the support given to vivisection by the clergy we would ask the Church Anti-vivisection League for proof of this alienation. Also, can the League point to any definite condemnation of vivisection by any branch of the Church? It may be argued that neither has the Church approved of it, and she has not in so many words; but with regard to the relation of animals to man various divines have spoken clearly. St. Thomas Aquinas: Summa, Q LXVI., Artic 1. As to whether man has a right of dominion over animals, &c.: "Per rationem et voluntatem potest uti rebus exterioribus ad suam utilitatem, quasi propter se factis, semper enim imperfectiora sunt propter perfectiora." St. Augustine, writing of animals, says: "Justissima ordinatione Creatoris et vita et mors eorum nostris usibus subditur." To come down to later times the Rev. Stephen Hales was not only a cleric but a vivisector and a most accomplished physiologist. We should say that these authorities would weigh more with the metropolitan clergy than the manifesto of the Church Anti-vivisection League, and to this body we wish to point out that no portion of the Hospital Sunday Fund is devoted to any medical school, so that we fail to see how by contributing for the relief of the sick and needy the clergy subsidise vivisection. Useless cruelty, of course, is to be avoided as being irrational. In saying this we know that our opponents will say, "Exactly—all reason and no heart." But we use the word irrational in its philosophical sense. No one deprecates cruelty more than we do. Ludwig, perhaps the greatest physiologist and most persistent vivisector that ever lived, was noted for his humanity and love of animals. We would commend to the notice of the Church Anti-vivisection League a sermon preached at St. Peter's, Vere-street, on Oct. 25th, 1871, by the then incumbent, the Rev. J. C. Coghlan, and a very admirable paper which originally appeared in the *Irish Ecclesiastical Record*, "Vivisection and Theology," by Mgr. J. S. Vaughan.

"THE OPTICIAN v. THE OPHTHALMIC SURGEON."

WE are glad to find that our remarks on "The Optician v. the Ophthalmic Surgeon," in a recent number of THE LANCET,[1] have been taken in good part by a well-known optician, whose letter we print, and who appears to coincide with the views we expressed. It is precisely because (to use the words of our correspondent) the advances of our knowledge during the last few years have "lifted the whole matter into the professional sphere" that it behoves opticians to be chary of prescribing glasses, however competent they may be to determine the precise lens, or combination of lenses, required. Even in this respect there are limitations to their powers, for the optician would not be justified in employing atropine, without the use of which in many cases the appropriate glasses cannot be ascertained. Ophthalmic surgeons have reason to be grateful to the opticians for the beauty and perfection of the lenses they supply, and for many useful suggestions they have made in regard to mounting, and we are sure that in the long run those opticians will thrive best who will devote their energies to the perfecting of their apparatus and the development of the resources of their art. Though they may be thoroughly competent to deal with the physical aspect of the question, additional and special medical knowledge is required to determine whether it is advisable to *adopt* these very measures which, from a physical point of view, leave nothing to be desired.

PROPOSAL TO REDUCE NOTIFICATION FEES.

THE medical profession, to an extent probably in excess of any other, performs voluntary work for the public good, and from time to time the profession receives in return from that section of the public, for which in large part it labours gratuitously, indications of the want of appreciation in which its professional services are held. Whether there is any relation of cause and effect between this gratuitous labour and this want of proper appreciation is a question we cannot now stay to discuss, but we wish to draw attention to the recently expressed views of certain district councillors in reference to notification fees. The rural district council of Halesowen have had, they tell us, under their very serious consideration the large amounts paid by them to medical practitioners for notification under the Infectious Diseases (Notification) Act, 1889. As a result of their deliberations they are of opinion that a smaller fee than 2*s*. 6*d*. would sufficiently remunerate the practitioners who are not medical officers of any public body or institution for their trouble, and they also think that there is need for only one uniform fee for notification. In few words, the Halesowen district councillors consider the sum of 1*s*. an adequate recompense to any medical man for notifying a case of infectious disease to the local sanitary authority, and they are apparently endeavouring to convert other sanitary authorities to their way of thinking, in the hope of inducing the Local Government Board to take measures for bringing a Bill before Parliament to amend the Notification Act in the sense referred to.

[1] THE LANCET, May 9th, 1896.

Digitized by Google

We imagine, however, that the Local Government Board have far too great an appreciation of the value of the notification of infectious diseases and of the services rendered by medical men to the State in this respect to risk the breaking up of the system of notification by encountering the hostility of the whole profession, and we may further assure the councillors that the medical profession will if necessary take steps to prevent any further reduction in notification fees. If the rural councillors who propose the alteration have no idea of the amount of money which has to be expended on the education of a medical man before he can properly diagnose cases of infectious disease, and of the responsibility and strained relationships which notification often entails, we are sorry for the rural district over which these rural councillors preside.

THE EPILEPTIC COLONY AT CHALFONT: LAYING THE FOUNDATION-STONE OF A HOME FOR WOMEN.

ON Tuesday last, May 26th, the foundation-stone of a Home for Women was laid with full Masonic honours by Lord Addington, Provincial Grand Master of Buckinghamshire, assisted by the Provincial Grand Officers. About 200 visitors journeyed from London and drove through very picturesque country from Chorley Wood Station. About eighty Freemasons were present, including many medical men, and their Masonic garb added picturesqueness to the interesting ceremony. Among others present were Mr. Passmore Edwards, Archdeacon Sinclair, Dr. Buzzard, Dr. Ferrier, Dr. Shuttleworth, Dr. Fletcher Beach, Dr. Aldren Turner, Dr. Colman, Dr. Morton, Dr. James Taylor, Dr. Page May, and Mr. George Cowell. At the close of the ceremony an interesting and eloquent account of the aims and intentions of the National Society for the Employment of Epileptics was given by Mr. Micholls, chairman of the Executive Committee. It appears that there are at present thirty-six male colonists, who carry on chiefly market gardening, carpentering, and shoemaking. The remarkable generosity of Mr. Passmore Edwards (who erected the first permanent home for men) has again been shown in his undertaking the cost of this new Women's Home, which will accommodate twenty female colonists whom it is proposed to employ mainly in the laundry, at needlework, and in the dairy. We understand that Mr. Edwards also intends to add a Home for Epileptic Children. The remarkable progress made by the colony in less than two years from its inception indicates clearly how great a need there must have been for such an establishment and that there is a great future in store for it, for it not only gives shelter and protection to a class of sufferers whose lot is often miserable in the extreme, but, by providing them with useful productive occupation under favourable circumstances, prevents, or at least retards, the dulling of the faculties, which is frequently the saddest accompaniment of the disease. Those who were present in the autumn of 1894, a few months after the colony was opened, could not fail to have been struck with the difference in the expression of the faces. Almost all showed to the skilled observer indications of their terrible malady, but there was an alertness and a look of independence about many of them which was wanting before, whilst their appearance suggested that physically they were in better health than many of the visitors. We were informed that there has been no case of serious illness among the colonists apart from the immediate results of their fits, a striking tribute to the healthiness of the site selected by the committee. It was stated by Dr. Buzzard that the medical staff were fully satisfied with the beneficial effect that residence at the colony had had on the epileptic attacks. The work, however, cannot be carried on without considerable expenditure. The labour of the colonists requires much supervision from non-epileptic skilled workmen, and supervision is also required for protecting the colonists when attacked by fits and for maintaining order and discipline. It is certain that the erection of the new Home for Women in the neighbourhood of the men's home will necessitate increased watchfulness and probably a larger staff, proportionally, than is at present adequate. Dr. Buzzard mentioned the necessity of providing also for a resident medical officer—a need recognised by the Committee in their last report, and he strongly appealed for funds to enable a suitable residence to be erected. No one who has had practical experience of institutions of this kind will question the urgency of this proposal, which becomes doubly necessary now that the committee have decided to admit women as well as men to the same colony. Lord Addington, in responding to a vote of thanks, intimated his intention of specially helping towards the establishment of a residence for a medical officer, and when next we have occasion to refer to the colony it is to be hoped that others will also have lent a hand and that this most necessary addition may have been made. Subscriptions are urgently required both for further equipment and for current expenses and should be sent to the secretary, Mr. Gaskell, National Society for the Employment of Epileptics, 12, Buckingham-street, Strand.

IMPLYING REGISTRATION.

WE have submitted the recent decisions in the cases of Reg. *v.* Frickhart and Reg. *v.* Bridgewater for his opinion to a legal friend well acquainted with our own profession. He writes as follows:—In these two cases the courts have held that the mere use of an unregistered foreign diploma in connexion with medical practice does not constitute such a "wilful and false" pretending to be registered as to bring the user within the fortieth section of the Medical Act of 1858. The case of Reg. *v.* Bridgewater (heard by a Divisional Court on the 19th inst.) does not present any special features beyond the fact that Mr. Bridgewater used, in addition to the letters M.D., the explanatory letters U.S.A. That the law upon this point is not in a perfectly satisfactory position may be taken to be proved by the observation of Mr. Justice Collins who remarked in deciding this case that the law was "in a fog." The difficulty is that of determining what amounts to a representation that the practitioner is registered. When the statement made is absolutely false or fraudulently misleading the Courts will convict, but when the statement actually made is true, and the only thing that misleads is the very natural inference that a medical qualification actually held is registered, the Courts have manifested great reluctance to press the law against individuals. This feeling is a very natural one and one of which account should be taken by those who are responsible for putting the law in motion. There is a tendency both within the medical profession and outside it to look upon the offence of falsely pretending to the possession of medical qualifications as an encroachment upon the privileges of qualified men, and this, although it is true enough, is not a very instructive view of the position. The status of a registered medical practitioner is, in a sense, a privileged one, but the privilege is not conferred for the benefit of the privileged class but for the benefit of the general public. If ignorant or unskilful persons are permitted to practise on the public the public must suffer, and it is for the protection of the public against this form of suffering that the Register is published and protected by penalties against falsification. It is, therefore, a very inadequate view of the statute to look upon it merely as the charter of the medical profession. It is this only because it is much more; the protection of the public is its end and the protection of the profession a means

Digitized by Google

to that end. This line of reflection suggests the expediency of shaping charges of the kind referred to as far as possible in such a way as to bring into strong relief the public mischief which results from any relaxation of the rules regarding registration or the placing of any obstacle in the way of a thorough and efficient working out of the registration scheme. It is, no doubt, possible to show by argument that in this matter the interests of the medical profession and the interests of the public are indistinguishable and that what injures the one injures the other. Hence the wisdom, at any rate until the law has emerged by successive decisions out of the "fog" and taken shape in clearly defined rules, of submitting to the courts only such instances of encroachment upon the sphere of medical practice as affect in a way too plain for discussion the public interests which it is the object of Medical Acts to protect.

THE HEATH SCHOLARSHIP.

BY the will of the late George Yeoman Heath, Professor of Surgery in the University of Durham and President of the Durham College of Medicine, a sum of £200 is awarded every second year for a surgical essay. The trustees of the scholarship have announced that the second award will be given to the writer of the best essay on "Congenital Deformities, their Pathology and Treatment." All graduates in medicine or in surgery of the University of Durham are eligible to compete for this scholarship, and the essay which must be type-written or printed, should be delivered to the trustees not later than March 31st, 1898. The essay, together with any specimens, drawings, casts, microscopical preparations, or other means of illustration accompanying it, will become the property of the College, though by permission, the essay may be printed for general circulation by the Heath scholar. This is one of the most valuable surgical prizes in the kingdom, and the competition should be keen.

THE ROYAL INFIRMARY OF NEWCASTLE.

THE prominence and activity of Dr. Philipson in Newcastle and its school of medicine—a part of the University of Durham—give exceptional interest to the fact of his resignation on the score of age. The rule of the infirmary requires resignation at sixty years of age—a time of life when a physician is now often at his best, with the advantages alike of youth and age. The post held for twenty-eight years so honourably by Dr. Philipson is naturally one of the prizes coveted by aspirants to professional fame in the city of Newcastle, which has long been noted for men of strength in the profession. The committee have the responsibility of the succession. They will have no excuse for not making a fit appointment. It is understood that Dr. George Redmayne Murray and Dr. Thomas Beattie are candidates for the post. The election will be watched with more than local interest.

PAIN IN CASES OF TUMOUR OF THE SPINAL CORD.

PAIN has generally been looked upon as one of the most constant symptoms accompanying tumours of the spinal cord. In the March number of the *Journal of Nervous and Mental Diseases* Dr. Pearce Bailey reports two cases which were remarkable by reason of the absence of pain which characterised their progress, and while they do not permit any general rule to be formulated with reference to this point they are interesting as a valuable contribution to the symptomatology of an important class of cases. The first was that of a woman sixty-five years of age who died from nephritis and pneumonia and in whom a tumour was discovered involving the dorsal region of the cord between the seventh and eighth roots. This tumour had given rise to no symptoms, either motor or sensory, and was, indeed, accidentally discovered in the course of a systematic examination. Its character was that of a psammoma. The second case was also that of a female patient, twenty-nine years of age. She had had between 1889 and 1893 several operations for "tumour," but the nature and situation of these could not be discovered. Ever since 1889 she had been troubled with recurring attacks of paralysis and numbness affecting all four extremities. She made a good recovery from several of these, but she was readmitted to the hospital in 1895 with the history of the sudden onset of the state of paralysis in which she was when admitted. There was in all four extremities extensor paralysis with flexor contracture—a condition, indeed, suggesting peripheral neuritis; but the knee-jerks were active, and there were cystitis and incontinence of urine. She denied ever having been subject to severe pains. The patient died with lung symptoms and suppression of urine, and at the necropsy a large quadrilateral mass was found on the ventral surface of the dura mater in the cervical region, involving the first four cervical roots. The dura mater itself was only slightly thickened. The tumour was apparently a degenerated gumma, and there were considerable changes in the neighbouring vessels and ascending and descending degenerations in the cord itself. The writer refers, in conclusion, to a case reported in *Brain* by Dr. Michell Clarke, also of spinal tumour without pain, and he is of opinion that the presence or absence of pain, and also the degree of its intensity, may have some relation to the slowness or rapidity of growth of the tumour.

"RETURN" CASES OF SCARLET FEVER.

THIS interesting subject seems at irregular intervals to attract the attention of the public and to call for some comments in our columns; but we are glad to see that the lay press is now approaching the matter in a fair spirit of inquiry and that the occurrence of so-called "return" cases is not at once followed by indiscriminate charges of neglect against the hospital authorities. The most recent group of cases which are explicable on a thesis of infection being conveyed by discharged patients from a fever hospital is reported from Richmond, and there certainly appears to have been a very remarkable chronological sequence in some of the cases. A patient, after eleven weeks' isolation in hospital, was discharged presumably free from infection, but five days later a sister was attacked by the same disease and three days after this—i.e., eight days after the first patient's discharge—three other children were attacked. All these patients were isolated for eleven weeks, but within a week of their return home the mother of the family was attacked. It is very strange that this series of cases should occur in the same family, and it would certainly appear probable that some of them were connected with the return of patients from the hospital. We are not in possession of all the facts necessary to form a judgment on the merits of this little outbreak, but if the laundryman in whose house the cases occurred, and who has doubtless suffered much hardship in connexion with the outbreak, considers, as apparently he does, that he has cause of complaint against the hospital authorities, it will perhaps be better that inquiry should be made as to whether all practicable precautions are taken at the hospital in question, and whether proper disinfection of the house was performed after the removal of each case or group of cases—in other words, that the question should be investigated from both sides. It would seem improbable that the whole series of cases is to be explained by carelessness on the part of the hospital authorities, as after the occurrence of the first "return" case the authorities would have been especially careful as to disinfection, &c. It is interesting in connexion

Digitized by Google

with this outbreak to reflect as to what would have been the position of the laundryman had none of the cases been isolated. In the first instance, it might have been necessary to suspend business operations during the presence of a case or cases of infectious disease on the premises, and having regard to the fact that apparently the majority of the cases, and certainly the mother, were exposed to the disease on more than one occasion, it does not seem probable that had there been no hospital isolation all the family would have taken the disease almost simultaneously. While therefore we sympathise in every way with the laundryman, it appears to us that his position might have been much worse had there been no isolation hospital in existence. One of the main objects of isolation hospitals is to enable the business of an establishment to be carried on after the removal of a case of infectious disease to hospital and the completion of disinfection of the premises.

THE GENERAL MEDICAL COUNCIL.

AT the forthcoming meeting of the General Medical Council Mr. Pridgin Teale intends to bring forward the following motion: "That the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it are not only unjust to the student but damaging to medical education; therefore, that the time has arrived when the General Medical Council should consider: (*a*) how far examinations and the occasions of rejections can be reduced in number, and (*b*) how far, whilst maintaining effective examinations in those subjects which it is essential that every medical man should 'know' and 'retain the knowledge of,' it is possible to withdraw from the sphere of public examination several other subjects which it is desirable that every medical man should 'know about,' but with the details of which he need not permanently burden his mind, the 'bird's-eye-survey' of such subjects being ensured by compulsory short courses of lectures with class examinations certified by the teacher."

THE LIVERPOOL LADIES' CHARITY AND LYING-IN HOSPITAL.

THE angry controversy which has been raging between the board of management of this charity and the late medical staff can if persisted in only end in the complete extinction of the institution. The medical profession in Liverpool is unanimous in its condemnation of the harsh and unjust treatment meted out to the late staff by the board. The attitude of the board towards the staff has not only been offensive but totally unworthy of a body posing as competent to manage the affairs of a public charity. If strong language has been used in the local press by the friends and sympathisers of the late staff, it is, under the circumstances, justifiable. When such epithets as "brutal," "inhuman," and other like phrases have been freely applied to members of our profession for not lending themselves to the views of these gentlemen small blame attaches to the friends of the late staff for hitting out from the shoulder. The board of management consists nominally of ten members, but practically of only four or five. All the letters received by the medical staff purporting to come from the board of management are alleged to have been written by the president and in some instances to have come from him alone and not from the board. The other governing body is the committee of ladies, who are mostly the wives of the members of the board of management; the form of confidence reposed by them in the late staff is instanced by their appreciation of charges of neglect of duty occasionally preferred by the staff against the midwives of the charity; these charges resulted usually in judgment being given in favour of the midwife, in direct opposition to the report of the medical officer who may have made the accusation. A climax of feminine interference was reached by the expression of opinions "on the pattern of an instrument selected by the staff and criticising their professional actions." We are strongly of opinion that, as the medical staff have resigned, the president and one or two other members of the board who have associated themselves with his course of action should also resign. A meeting of the subscribers to the charity should then be held, when means could surely be found whereby the government of the charity could be reconstituted on a satisfactory and proper basis.

NEWSPAPER THERAPEUTICS IN AUSTRALIA.

WE regret to see in the *Argus* columns of letters by Dr. Gresswell, Mr. Moloney, Mr. Duncan Turner, Dr. Louis Henry, and other well-known Australian physicians discussing the use of the cold bath in typhoid fever. Dr. Gresswell treats his audience, which is the public, to arguments based on albuminous infiltration and fatty degeneration. Surely it is most unseemly that such practitioners should set the bad example of discussing important questions in therapeutics in the newspapers. We shall not pursue this note of censure further than to remind them that they are, no doubt thoughtlessly, violating the best traditions of the profession.

POST-MORTEM INSTRUMENTS IN PUBLIC MORTUARIES.

THE St. James's (Piccadilly) Vestry have passed unanimously the following recommendation of their Public Health Committee:—"That the necessary instruments for complete post-mortem examination be provided for use in the mortuary, Dufours-place, by the vestry, the same being required in the interest of progress, apart from the tribute to the medical profession, the committee believing that it is desirable to expedite and perfect any measures bearing upon the spread of science as affecting the public weal, the detection of crime, &c. The instruments used for this purpose are cumbrous and are not, as a rule, possessed in their completeness by medical men, who are only on rare occasions called upon to assist the authorities in medico-legal investigations." We hope that the other vestries which have not yet supplied these essentials for post-mortem examinations will follow this enlightened example.

PERSISTENT RECALCITRANCY.

THE maintenance towards a matter of any attitude which has been shown by repeated experience to be wrong is, to say the least, sheer folly. When the matter is one which seriously affects the health of the community such action becomes almost criminal. Such, we take it, is the attitude of boards of guardians towards the Vaccination Act, which leads them persistently to refuse to accept the dictum of the facts which are ever coming before them in the shape of data from one and another centre of small-pox activity to show that the one unique specific against the inception of the disease in a fatal form, and oftentimes, as proved by comparative data, against attack in any form, is vaccination in infancy, and, better still, this operation supplemented by revaccination in later years. The plain facts, as shown by recent data from Gloucester and other places, were laid before the Hackney board of guardians by one of their number early this month, and much discussion followed the motion to rescind a resolution passed in 1889 to withhold action under the Vaccination Acts pending the sitting of the Royal Commission on Vaccination. The old points of resort to compulsion and interference with the liberty of the subject were among those brought up against the motion, the fact being ignored

Digitized by Google

that education has now to be enforced, and is in its way eminently an interference with liberty of conscience. The law of vaccination is by no means an isolated example of the requirement of enforcement of a beneficent measure to ensure its general success. With nearly 30,000 unvaccinated children in the union of Hackney the postponement of action in relation to defaulters may at any moment find the district visited by small-pox. When the inaction of a public body in opposition to the law of the land endangers the health of the community it seems high time that body was relieved of the power of inaction and the duty unfulfilled handed over to those who will faithfully carry it out. The anomaly of a sanitary body doing its best to stamp out disease which the recalcitrancy of another local body has fostered is one that should cease. And in this connexion the State has a duty which needs to be acted upon. When State and local authorities are alike inactive the anti-vaccinationist flourishes and the seeds of future epidemics of small-pox are sown broadcast. Perhaps the Vaccination Commission may report some day and tend to hasten the coming in of better things all round.

SANITARY AUTHORITIES AND THE VACCINATION ACTS.

THE desire on the part of sanitary bodies to have in their hands the administration of the Vaccination Acts seems to be growing. We notice that it is now stated that the Lewisham district board of works are about to apply to the Court of Queen's Bench for a writ of mandamus to compel the Lewisham board of guardians to enforce the Acts. This, we take it, is but another way of expresssing the view that the duty would be better entrusted to the board of works themselves. We trust that in many more quarters there may rise up the demand on the part of health bodies for the better administration of the Acts now that we may be exposed next winter to a general small-pox epidemic. It is a distinctly healthy sign that our local sanitary guardians are growing keenly alive to the absurdity of themselves using every effort for the extinction of small-pox, and spending the ratepayers' money on isolation hospitals and the like, while the Poor-law guardians are quietly sitting by and allowing people to disregard the law, with resulting suffering, death, and expense.

ACTION FOR MALPRAXIS AGAINST AN UNREGISTERED "DENTIST."

AN action (to which allusion was made last week in our Birmingham correspondent's letter) has recently been tried at the Birmingham county court in which a labourer sought to recover damages for unskilful treatment from a druggist who was not a registered dentist. The facts of the case are briefly these. The plaintiff in June of last year went to a branch establishment belonging to the defendant to have a tooth extracted. He was seen by an assistant, whose name, also, does not appear on the Dentists' Register, and who made a fruitless endeavour to remove the tooth, and then suggested that the plaintiff should go to a proper dentist to get the remaining portion of the stump extracted. As far as can be gathered from the report the face and neck were swollen at the time of the operation. On the following day a medical man was called in and he stated that the bone had been splintered by the attempt to remove the tooth. After being five weeks under the care of the medical man the plaintiff went to Queen's Hospital, where some necrosed bone was removed, the patient not being able to resume his work until April 15th of this year. For the defence a dentist was called, who stated that he had known the assistant for four or five years and considered him a competent operator. In reviewing the facts of the case it would be difficult to say whether the necrosis was the result of the operation or the condition calling for extraction of the tooth, and, still further, it would be difficult to say whether the operation was performed skilfully or unskilfully. The point, however, which must not be overlooked is that there was no evidence beyond that of the dentist called for the defence that the assistant in question possessed the necessary skill. He was not registered, and admitted in his evidence that he had not been apprenticed to a dentist, so that we may certainly question whether he possessed the requisite knowledge. The case is one of those which help to point out the fact that better legislation is required to guard the public against unqualified practitioners whose knowledge is generally but slight and whose skill can usually be gauged at about the same standard.

FEVER AT MIDDLESBROUGH.

THE experience of Middlesbrough in the matter of fatal fever during the last twelve months has not been a happy one, judging by the successive returns of the Registrar-General issued in that period. Up to the close of last year the deaths from fever showed increasing prevalence, and the months that have since elapsed demonstrate a further increase, the first three months of the present year having seen a score of deaths from fever in the borough. In the face of these facts the action of the town council at its first meeting in the current year attains a special significance. The question of the transmission of the annual reports of the medical officer of health to the Local Government Board was raised, and it was asserted that such transmission would probably end in the council having to carry out the recommendations of its health adviser. The council had some time ago even gone so far as to refuse to accept repayment of a portion of the health officer's salary in order to avoid the need of sending up to the Whitehall authorities the annual productions of the medical officer. The requirements of death registration are, however, inexorable, and the facts which they bring to light in the case of Middlesbrough are the more likely to appeal to headquarters by reason of the wilful withholding of local reports. "Where ignorance is bliss 'tis folly to be wise" is not, we trust, likely to be the maxim of the central authority, and many a searching inquiry of a helpful nature has been set going by circumstances far less provocative of State intervention.

ACCIDENTS AND INEXPERIENCE.

THE very sad boating disaster which cost the lives of three persons last Saturday on Lake Windermere cannot fail to excite in every mind the keenest regret. It is further noteworthy as being typical of a class of accidents which is absolutely inseparable from almost any form of athletic recreation so long as obedience to the calls of caution and experience is not accepted as the governing principle. Whether it be the management of a sailing boat—and much more if this be a racing cutter—the climbing of a peak, a long swim, a ride on a horse or a bicycle, a row on the river, or a physical effort whatsoever or wheresoever, requiring skill in him who makes it, this rule holds. The novice must be content with learning; if he is not, no authority or act of law which does not also forbid his exertions can save him from getting into trouble. We do not ignore the duty of warning which belongs to professional instructors. The Alpine guide, the boat owner, and a hundred other experts must share this responsibility, but still another factor is required for the safe attainment of success—one who will listen to advice. We trust that a reasonable caution will still be in time for any who shall seek healthy recreation in various forms of sport this summer. At the inquest, which was held on May 25th, the jury, after returning a verdict of "Accidental death," recommended the local authority to prohibit the letting of

Digitized by Google

yachts unaccompanied by a boatman accustomed to the lake under penalty of forfeiture of the licence, and also an official inspection of yachts let out for hire in order to make sure that they were fitted with efficient water-tight compartments.

MEDICAL CERTIFICATES AND BOARD SCHOOLS.

THE example of the London School Board has infected one of its near neighbours. Alfred Barnes, of Church-street, West Ham, was summoned before Mr. Baggallay because his child did not attend school. He handed in a duly signed medical certificate stating that the child was unfit to attend school. The School Board authorities of West Ham refused to accept this as the nature of the disease was not stated. More than this, the School Board officer advised Mr. Barnes to change his medical man. Now, apart from the rudeness of the Board in refusing to accept a document which it has no right to demand, we contend that, in addition, it has no right to know what is the matter with any child. That is a confidential matter between the medical man and the patient or the patient's guardians, and we consider Mr. R. Brinsley Hunt, the medical attendant, was perfectly right in refusing to state on the certificate the nature of the disease. We do not expect courtesy or anything else except a constantly increasing rate from a School Board, but we do from a magistrate. Mr. Baggallay is reported as saying that "Dr. Hunt was very foolish and the School Board officer very wise. In respect to the remark of the officer to Mr. Barnes, if he (Mr. Baggallay) had been the School Board officer he would have said the same thing," which we can well believe after reading the rest of Mr. Baggallay's dicta. The summons was withdrawn, and thus another School Board has "incurred the odium of unsuccessful legal proceedings." Mr. Hunt is to be congratulated, and we hope his example will be studiously followed.

EASTBOURNE AND THE VACCINATION ACTS.

AT length, after some years of neglect of duty, the Eastbourne board of guardians have resolved to put the Vaccination Acts into force. This decision was reached at the meeting of the board on the 22nd inst., after a division upon a motion brought forward by Miss Brodie Hall and seconded by the Rev. E. E. Crake. Miss Brodie Hall referred to the "terrible object lesson" with which Gloucester had furnished them and pointed out that small-pox might invade any town, however well equipped in other respects, if the inhabitants were deprived of the protection afforded by vaccination. Mr. Crake protested against the indifference to this crucial question hitherto displayed by the board, and especially referred to the serious danger to the schools and colleges of Eastbourne which would be caused by an outbreak of small-pox in the town. It came out in the discussion that the vaccination officers had received instructions to enforce the Acts in accordance with a resolution passed on May 25th, 1893; but why these instructions had not been carried out did not transpire. One speaker (Mr. Luck) averred that the reason for the delay in the issue of the report of the Royal Commission was "because the evidence was dead against the vaccinationists." Dr. Adams said that "if they were to take six vaccinated children of six months old and six children of the same age who had not been vaccinated, the anti-vaccinationists would not dare to expose the unvaccinated to the infection of small-pox." Referring to remarks by Mr. Luck, Dr. Adams said that the medical profession was in favour of vaccination because they knew it was the best protection from small-pox that they could give to their children. The resolution to enforce the Acts was carried by thirteen to eight. The attitude hitherto assumed by Eastbourne on this question has always seemed to us a remarkable thing; for if small-pox were to invade the town and spread amongst the unvaccinated children, as it has done at Gloucester (where the proportion of the unvaccinated was no higher than at Eastbourne), this charming seaside resort would receive a blow to its prosperity from which it would take years to recover.

FORMATION AND STRUCTURE OF THE OPTIC NERVE.

IN an article contained in the April number of the *Journal of Anatomy and Physiology* Dr. Arthur Robinson of Owens College gives an interesting account of the formation and structure of the optic nerve derived from his researches on the embryos of man, the rat, cat, ferret, sheep, and rabbit. He accepts the view that the fibres of the optic nerve do not, as some have thought, arise from the epithelial cells which constitute the primary outgrowth from the brain, but holds that they spring chiefly from the cells of the retina which shoot up towards the brain but in part from the brain growing down to the retina. The optic stalk itself is composed essentially of protoplasmic substance which develops into retiform sustentacular tissue and becomes converted into the optic nerve by the passage of nerve fibres through its walls, the fibres being protected and supported by the external limiting membrane of the stalk. The specimens examined by Dr. Robinson showed that at their first appearance the nerve fibres are found in the stalk only in its retinal portion, and even in the later stages they are most abundant near the retina. When the invasion of the stalk by the nerve fibres first occurs they are limited to the ventral wall, and it is only when the canal of the stalk undergoes obliteration that the fibres are found in the dorsal wall of this process. He draws the conclusion from his researches that the retina is a portion of the brain wall specially situated and modified to the proper performance of its function; and inasmuch as it is an outgrowth of the ventral part of the lateral wall of the thalamencephalon the retina may be looked upon as a modified basal ganglion and the optic nerves are association bundles bringing it into relationship with other parts of the brain.

THE ILLNESS OF SIR J. RUSSELL REYNOLDS.

WE regret to learn on going to press that no improvement has taken place in Sir J. Russell Reynolds's serious condition.

A NURSING EXHIBITION will be opened at 2.30 P.M. on Monday, June 1st, in St. Martin's Town-hall, Charing Cross. The exhibition will remain open till Saturday, June 13th, during which period, in addition to the exhibits relating to the care of the sick and injured, there will be various attractions for visitors in the way of music, Roentgen ray demonstrations, &c.

THE Colonial Office is informed by telegram from the Governor of Hong-Kong that 76 fresh cases of bubonic plague occurred in the colony in the week ending May 26th, and that the number of deaths from the plague in the same period was 68.

THE Metropolitan Counties Branch of the British Medical Association will hold a conversazione in the Natural History Museum, South Kensington, on Thursday evening, June 18th.

THE new buildings of the Croydon Borough Hospital, Waddon, will be opened on Saturday, June 6th.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XXI.

The Adjourned First Meeting of the Members.—Its Action.—A Metrical Squib.—The Refutation by the College of the Charges brought against it.

THE Members of the Royal College of Surgeons of England re-assembled on March 4th, 1826, when Mr. William Lawrence again took the chair.

The business of the meeting was to receive a report from the committee which had been appointed at the previous meeting to prepare the petition to the House of Commons. Mr. Tyrrell, the chairman of that committee, said that, although they had received no instructions to that effect from the Members, they had approached the Council of the College asking them to join in the application to Parliament. These gentlemen having contemptuously refused, he proposed that the opinion of counsel should be taken as to the best mode of applying to the Legislature.

Wakley again made a forcible speech, in which he pleaded for action, the necessity for drastic reform being urgent. He read a long amendment to Mr. Tyrrell's motion, but that gentleman was ready to accept Wakley's suggestions, and with the leave of the meeting, altered his original resolution so that it read as follows:—

"That the committee be at liberty generally to take such steps as they think fit to remedy the abuses now existing in the Royal College of Surgeons; and that they shall call a general meeting of the members whenever they shall think it advisable."

Wakley seconded the resolution, which was carried unanimously. A subscription was then opened to defray the expenses of any step the committee might desire to take.

This, the first general meeting of the College, was to lead to important developments. The various steps that were taken by the reformers and the methods employed by the College authorities to arrest the progress of the movement will all be found chronicled in THE LANCET, and need not be here described more fully. Wakley's share in the movement is quite clear. He summoned the first general meeting by advertisement which he inserted himself. He persuaded Mr. William Lawrence, a member of the staff of THE LANCET as well as a hospital-surgeon, to take the chair at the meeting, knowing that in this way he would arouse the proper spirit of instructed reform and not merely turbulent clamour for nothing in particular. It was Wakley's speaking at the meetings which led to definite steps being taken. Had it not been for his vigorous words of contempt at the passing of mere condemnatory resolutions, the meetings would have been content with effecting that much; but they followed in his lead, and found themselves promptly committed to an appeal to the Government for reddress.

Mr. Abernethy, who was the mouth-piece of the Council in their very natural refusal to join the Members in the agitation for a new charter, was made the subject of several humorous attacks in THE LANCET, otherwise Wakley used his paper impartially. He printed the opinions of the reformers whom he represented, and whom he really led, but he gave equal space to any reply that came from the College. Mr. Abernethy was not put forward for the College because the great surgeon was the most reactionary Tory on the Council. He was nothing of the kind, and often his written or spoken words showed that he sympathised with many of the complaints that were made by the general body of the corporation against the existing management of the College. But Mr. Abernethy was a masterful man and an intellectual aristocrat. He did not approve of any opposition to a system of government for which he was partly responsible, while he belonged to a picked body of surgeons and sincerely believed that persons not so selectly situated possessed a lower order of intelligence and could not, consequently, expect to be entrusted with the conduct of their own affairs. His colleagues chose him as their spokesman because of his great public reputation and pronounced taste for fighting. Popular with the students and the best surgeon at the great hospital of St. Bartholomew he had an enormous public fame for honesty and bluff wit and a great scientific reputation, as the person upon whom the mantle of John Hunter had seemed to fall. The following verses on him from Wakley's pen did not constitute a fair attack as they misinterpret Mr. Abernethy's attitude, but they are worth printing as no mean display of metrical skill. Doggrel they are, but they say what they mean:—

JOHN ABERNETHY, LOQUITUR.

We have decreed that there shall be in England but one station
At which young men shall 'grind to pass' and have our approbation.

With Scotland 'tis a different thing, you all know I am Scotch, sirs,
And for my clan I do not mind to shuffle, cheat, and botch, sirs.

In Scotland then raw lads may find three schools to one elsewhere, sirs,
And those who deem this law unjust may scout if they dare, sirs.

* * * * *

Ye stupid fools and blundering churls, who want our leave to practice,
Behold, I take the pains to tell what our new-fangled act is.

* * * * *

Moreover, 'tis our royal will, our most imperial pleasure,
As well to fill our classes out, as swell our bags with treasure,

That knowledge henceforth be unsound, to reason quite contrary,
Unless obtained sometime about the month of January;

No one shall dare to think or say that any man can truly
Acquire the art of lopping limbs within three months of July.

* * * * *

So fare ye well, confound ye all—may every ill infest ye,
If ye shall dare to make a stir or say we have oppress'd ye.

The verses, which are extracted from a long "poem," are unfair, but it must not be supposed that their injustice to their subject, had the significance of a deliberate libel. No one believed in the accuracy of that sort of attack; the quality of exact truth was not expected. The metrical squib was a survival of eighteenth-century habit. If you were taking a side in a row you wrote verses lampooning your opponent. He replied with a pamphlet. You hit back with an open letter. Possibly a duel ensued. More often someone of the school of Gillray interposed and limned you both ridiculously, the net result being that the audience laughed and the champions laughed.

The occasion of these verses was the presentation by Mr. Abernethy of the refutation by the College of the charges brought against them. This document is appended. It is long, but it is the categorical answer of the governing body to all the charges of gross mismanagement that had been brought against them, and it would be unjust to alter it by a syllable.

"ROYAL COLLEGE OF SURGEONS, IN LONDON.

"*Observations in Refutation of Charges, publicly made by certain Members of the College, against its legally constituted Authorities.*

"It is asserted that the College has not performed those duties for which it was incorporated.

"That this assertion is unfounded, will be acknowledged by all reflecting and unprejudiced persons, who compare the present state of surgery throughout the country, with that, which existed when the College received its charter in 1800; for it appears that the increased respectability of the profession may be principally attributed to the acts and regulations

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII. XIII., XIV., XV., XVI., XVII., XVIII., XIX., and XX. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, May 2nd, 16th, and 23rd respectively.

Digitized by Google

of the College. This advancement may be mainly ascribed to the more extended education which has been progressively required of the candidates for its diploma; to the zeal and talents of its professors, in displaying and communicating by public lectures, a scientific knowledge of the subjects connected with the healing art; and to the labour and time devoted to the explanation of the contents of its Museum; by which a strong desire for increase of knowledge has been excited.

"The inquiry into the professional education and attainments of candidates, has been rendered more strict in proportion to the general increase of knowledge.

"During one period of the late war, when the applicants for examination were unexpectedly and unprecedentedly numerous, in consequence of the demands of the public service, many candidates were necessarily examined at the same court; but since the peace, not more candidates have been admitted to examination at any court, than could be examined in an ample and satisfactory manner; and for some time past, each candidate for the diploma, has been separately examined in the presence and hearing of the whole court; which is now the established practice.

"The examiners have so frequently referred candidates to a continuance of their studies, as to induce students in general to think seriously of their examination, and to prepare themselves for it, by a proportionate degree of diligence.

"Had inquiry been made, it would have appeared, that the examiners have not any pecuniary interest in the admission of candidates as members; and it cannot be improper to mention, that the remuneration received by the examiners is a very inadequate recompense for the time and labour bestowed upon the execution of their arduous and important duties.

"There is no profession into which dishonest and dishonourable persons have not at times gained admission; but the council are not aware of a single instance of an empiric having been admitted as a member; and not until lately, has it been understood, that the College possesses the power of removing any member who has been guilty of disgraceful conduct.

"It has been made a subject of complaint, that certificates of summer courses of lectures are not received by the court of examiners. That certificates are not indiscriminately received from every anatomical teacher, and that certificates of attendance on provincial hospitals are not admitted by the court; and such regulations have been censured as unjust bye-laws of the College.

"The council have in the first instance, to correct this error. There are no bye-laws on these subjects; these are regulations of the court of examiners. The council have been assured by the court of examiners, that so many certificates of attendance on lectures had been presented to them, purporting to be signed by teachers wholly unknown to them, as to render it imperative to define the certificates which in their judgment, it would be proper with a view to the public good, and respectability of the profession, to acknowledge and to receive.

"The council believe, that not any persons except the court of examiners are able to judge correctly on this subject; and while they wish to correct the erroneous supposition of the regulations in question being bye-laws of the College, they cannot but give credit to the court of examiners for the most pure and conscientious motives; and for an earnest desire to promote the dignity of the profession; and necessarily the welfare of the community; in the legitimate exercise of their discretion on these subjects.

"The court of examiners, anxious that students should attend instructions capable of giving them enlarged and scientific views of their profession, knew not how they could obtain from distant places, any evidence of the teacher having, himself, received a liberal professional education, but by the means which they have adopted; yet, notwithstanding such regulations, it cannot be doubted that any member of the College, possessing in an eminent degree the requisite qualifications for becoming a teacher of anatomy, physiology, and pathology; which are united in the recognized schools; would so distinguish himself, as to justify the admission of his certificates. The regulations of the College must always change with the circumstances of the times.

"The subject of attendance on provincial hospitals, had repeatedly engaged the consideration of the court of examiners; but with every respect for, and the highest opinion of, the medical officers belonging to most of these excellent establishments, the council would witness with regret the indiscriminate admission of such certificates.

"The court of examiners, have under certain conditions, recognized attendance on the practice of some of those hospitals; and the council are of opinion, that it would injure the cause of chirurgical science, where the court of examiners to be controlled in the exercise of their discretion on this subject.

"In reference to the complaint of the Museum not being more freely and frequently opened to the public, and of the want of a catalogue; answers to such accusations are contained in the triennial reports from the Board of Curators to the council, in the last of which is the following summary of proceedings, with respect to the catalogue.

"'The following recital of facts will show the council how solicitous the curators have always been that the collection should be properly explained.

'When the Hunterian Collection was received by this College, it was accompanied by two catalogues; one, explanatory of the preparations in the gallery; the other, of the morbid preparations. These had been compiled by Mr. C. Clift, under the direction of Sir Everard Home, from old catalogues, formed under the superintendance of Mr. Hunter; as is proved by his hand-writing in many parts of them. The transcript must have appeared to the curators, and must be allowed, by every one, to contain a very excellent and perfect account of Mr. Hunter's views and opinions in the formation of his collection; though it must also appear very deficient in the explanation of the individual preparations.

'No one, however, supposed, until within a short time, that Mr. Hunter left any other writings of importance explanatory of his Collection, than the before mentioned two catalogues.

'On the completion of the Museum, and the admission of visitors, the want of a descriptive catalogue was soon felt and expressed; and the Board of Curators, in the year 1813, prepared a printed syllabus to gratify scientific inquirers.

'The Curators also consulted Dr. Shaw, who, at the instance of the Board, prepared a third catalogue of objects in the department of natural history.

'A descriptive catalogue of the preparations, which was earnestly desired by the Trustees, has ever been a desideratum of great interest and consideration to the Board of Curators, as may be seen by its minutes.

'The Board regarded Sir Everard Home, as executor of Mr. Hunter, to be the person most proper, and best qualified to undertake the task of preparing the catalogue, which he repeatedly engaged to do.

'At length, in 1816, it was proposed, that all the Curators should become joint labourers in this great work, when Sir Everard Home declared, that it was his special duty, and that he would admit of no participation in its performance. The result of his labours was the production of a synopsis, which, doubtless, the members of the Council have perused.

'When in 1817 Sir Everard Home became a Trustee, he resigned the office of Curator; and the Board, anxious for the completion of a descriptive catalogue of the contents of the Museum, resolved to engage the Conservator in preparing one under their own superintendance.

'In order to allow him more time for this undertaking, the Board appointed his son to be assistant in his ordinary duties. They directed that the specimens of monstrosity should be removed from the closet in which they were arranged, that it might be appropriated, during the necessary time, to the receipt of books, papers, and other things subservient to the preparation of the catalogue.

'The Board decided, that the contents of the galleries should be arranged in two divisions, each containing subdivisions, which sub-divisions should also contain series and sub-series.

'The Board further appointed Sir William Blizard, Mr. Cline, and Mr. Abernethy, to be a sub-committee for the special purpose of superintending the formation of the catalogue; to report to the Board from time to time the progress made in it, with such observations relating thereto, as they should consider proper; which sub-committee has presented to the Board the description of the first subdivision of the gallery, comprehending seventeen series, containing 261 preparations, which was approved by the Board, and also by the Trustees.

'When, however, the Conservator began his task of preparing the catalogue, he expressed the wish to obtain some of Mr. Hunter's manuscripts, and thus did the Board of Curators learn for the first time the extent and nature of the

Digitized by Google

manuscripts left by Mr. Hunter, with relation to his collection.

'The Curators, on applying to Sir Everard Home, were informed by him, that he had burned all Mr. Hunter's manuscripts, in consequence of a promise made to Mr. Hunter to that effect.

'Amongst these manuscripts were ten volumes in folio, viz., nine on the anatomy of animals, and one on vegetables. That Mr. Hunter considered these books to be valuable, and not otherwise than creditable to himself, may be inferred by three of them being placed on the table beside him, when his portrait was painted by Sir Joshua Reynolds.

'It is said, that Sir Everard Home has even burned Mr. Hunter's manuscript lectures, which he read to his class. But the Curators cannot believe that Mr. Hunter could intend that these works should be burned as unimportant manuscripts. It must, therefore, always remain a subject of deep regret, that Sir Everard Home should have felt himself bound by his promise to Mr. Hunter, to have carried destruction to the extent to which he is said to have done; yet Sir Everard Home has not felt the same obligation to destroy all the writings on morbid anatomy; for the Curators have obtained, through the interposition of the Trustees, two folio volumes, and two solanders of cases and dissections explanatory of a considerable number of the morbid preparations.

'These books contain a careful record of the symptoms and effects of disease during life, and the alterations of structure produced, as ascertained by examination after death. They are highly creditable to Mr. Hunter, as expressing that thirst for knowledge, which led him constantly to seek it by means which we know to be the most certain, but also the most tedious, laborious, disgusting, and unostentatious.'

"The want of a catalogue, as explained in that report, is, in the opinion of the Council, a most satisfactory reason why the Museum has not hitherto been more freely opened to the profession, and why it cannot be for some time, admitting the completion of that catalogue, to be of such paramount importance as the Council deem it to be.

"It may be further observed, that the study of comparative anatomy had been formerly so little prosecuted in this country, that, though many persons were consulted, none could aid in giving a description of the individual preparations in the Hunterian Collection. The Conservator has, however, for a considerable time, been engaged in such researches and inquiries, as have enabled him, not only to give an exact account of each preparation, but also to explain Mr. Hunter's intentions in the formation of his Collection; and the more the time of the Conservator shall be occupied in explaining the contents of the Museum to visitors, the longer necessarily must the completion of the catalogue be retarded.

"With respect to the Library, its formation has been the act of the College, and is intended to aid the professional inquiries of its members, for which purpose it will, when in a proper state, be opened.

"It may be added, that of the numerous applications made by members, for permission to refer to publications therein, every one has been most readily complied with; and the same may be observed of applications to examine and to make drawings from preparations in the Museum.

"With regard to the supposed indignity offered to the members at large, by their being admitted to the theatre by a door at the back of the building, the Council, aware that any want of respect to its members would be a failure of respect to the institution itself, did not imagine that umbrage would be taken by such an arrangement; at the same time they regret that the present construction of the building precludes the practicability of an alteration.

"It is proper to observe, that no official complaint or remonstrance on this subject has ever been made to the Council. Some years since, indeed, it was mentioned to the board of curators; upon which the members, during one course of lectures, were admitted to their seats from Lincoln's Inn-Fields, through the Museum; the dust occasioned thereby, was found to be injurious to the collection, in consequence of which, the present arrangement was adopted; certainly with a view to the comfort and convenience of the members, and for the preservation of the preparations. When the theatre was built, the great influx of persons into the profession, which has since taken place could not have been anticipated; and it was then thought that the building would be more than adequate to the accommodation of all who would attend.

"It is represented, that the constitution of the College has been the cause of the alleged injuries and grievances.

"The evident object of this representation, is the subversion of the present government of the College, and the substitution of elections to offices of control and responsibility, by members, who for the most part exercise the professions of apothecaries and accoucheurs. There can be little doubt, that in the event of such an innovation, the Institution would soon cease to be a College of Surgeons or of Surgery, and a system of continual intrigue and cabal amongst the profession in general would be introduced.

"The constituted authorities of the College are conscious that they have uniformly exerted themselves to increase the scientific knowledge and respectability of the profession; and that they have never been influenced by the unworthy motives imputed to them; had any of the members of the College expressed dissatisfaction at their proceedings, they would have willingly explained the reasons of their conduct, as well as their future intentions, and have altered whatever could have been shown to be wrong; but when meetings have been convened to subvert the Charter of the College, 'under the sanction of which," it is said, "injustice and tyranny have been perpetrated"—when, at these meetings, the most dishonourable motives have been attributed to the members of the Council, they feel it due to themselves to offer this brief, and they trust satisfactory, explanation of their conduct.

By order of the Council.
(Signed) EDMUND BELFOUR, Secretary."
"Lincoln's-Inn Fields, 26th day of April, 1826."

THE REPRESENTATION OF MEDICINE AT THE NATIONAL PORTRAIT GALLERY.

OF all the learned professions medicine is the happiest in having no history, or, rather, in not entering the history of political and national strife. The lawyer and the clergyman have time and again been the heroes of one party or other, and artists with brush or pen have won notoriety by a somewhat unholy alliance with the factions of the moment. The medical man has no concern with the inflicting of wounds, corporal or mental; his only task is to heal and prevent them. His enemies are disease and dirt, and victories over the common foe bring no such glory as is won by crushing the particular opponent of the moment. Nevertheless, the National Portrait Gallery contains not a few pictures of the famous physicians of the past, which bring to mind more clearly than before the personality of bygone leaders. Up in the topmost floor hangs the portrait of the coryphæus of the line, Sir William Butts, the physician of Henry VIII., and a very early Member of the Royal College of Physicians of London. The catalogue claims him as one of its founders, but that is hardly accurate, for he was not admitted until a year after its commencement. The humorous and pawky face that the scholar of Holbein painted from his master's original betrays clearly enough the Norfolk ancestry, and makes it possible to understand how he retained the favour of his somewhat irritable patient even though he dared to plead for statesmen out of favour. The portrait is interesting as that of the one physician whom Shakespeare names all through the plays, and he is characteristically pleading for Cranmer and calling the King's attention to the strangest sight:

> "The high promotion of his Grace of Canterbury,
> Who holds his state at doors, 'mongst pursuivants,
> Pages, and footboys."

It would be unfair to think of him as a fly in amber, but it is not unnatural to wonder why he should have been introduced into the play merely to speak three sentences and to hear from his master: "Butts, there's knavery."

The portrait of Harvey is perhaps the most interesting of all, though unfortunately hung so that the light is reflected from the glass and partially dazzles the view of the picture behind whatever efforts be made to find a satisfactory position. There are written very plainly on the face the irritability and nervousness which made his life unhappy and added sting to the neglect or contempt with which his discoveries were received. Aubrey is fully borne out in his description of his contemporary as, "like all the rest of his brothers, very cholerique, and in his younger days apt to draw out his dagger upon every slight occasion." "His

Digitized by Google

little eie, round, very black, full of spirit," still looks out from the canvas; but the hair, once "black as a raven," is here quite white, though the animation of the general expression has bated not at all. Like his predecessor Butts, he is one of the glories of Caius College, Cambridge, or, as it used to be, Gonville Hall.

Oxford can claim no genuine physician in the gallery, though Hunter was on the books of St. Mary's Hall for ten months. She has to fall back upon a fine painting by Van Dyck of one of the irregular army that hangs upon the wings of the medical forces. Sir Kenelm Digby was a very early experimentalist and of the keenest, but unfortunately he had the "infirmity," as a lady friend of his gently phrased it, of lying magnificently about his work. His famous "powder of sympathy," which "infallibly cured" all green wounds if first applied to the offending weapon, has a certain flavour recalling Count Mattei and coloured electricity, although powdered blue vitriol may, after all, have had some antiseptic and escharotic value. At the same time, he was keenly interested in medicine and a most fervent believer therein. Upon the whole, Oxford has more reason to feel proud of him as sea-captain than as physician, but as Radcliffe does not appear in the gallery the best must be made of Sir Kenelm Digby, and excuses found for his imagination in the huge forehead, which curiously recalls the face of Shakespeare, though wholly lacking in the balance of mouth and chin.

The eighteenth century is much more prolific of great names, though sometimes it may fairly be asked whether the intention of the trustees has been successfully accomplished. Their rule, as Earl Stanhope declared, was to admit "not a single portrait as to which a man of good education passing round would be under the necessity of asking, 'Who is he?'" Even a medical man of good education may be pardoned for a difficulty in recalling the chief facts in the lives of Saunders and Allen, and how much more a layman? Sir Charles Bell, bearer of a name long famous in medicine, whose work on nerves is claimed by many, and also by himself, to rank his name upon the same scroll as Harvey, stands up in most orthodox lecturing position, smiling with the thought that his "Anatomy of Expression" has been sent, by desire, to the Nabob of Arcot, bound in all the glory of red morocco and satin. What use the Nabob made of the work cannot be known, but if it interested him he was not unlikely to test its assertions by vivisection on a large scale without the aid of anæsthetics. No doubt the large red book beneath his hand is a pleasant reminiscence of his world-wide celebrity, but he should have held his Bridgewater Treatise on the Mechanism of the Hand in the other to complete the memorial. Side by side stand the two great London men, Hunter and Edward Jenner. The first portrait is copied by the brush of Jackson from the famous Reynolds in the Royal College of Surgeons of England and is too well-known to need description, especially the local colour delicately insinuated by "an anatomical preparation in a bottle, and the feet and ankles of a human skeleton." This local colour is secured for Jenner by a drawing of a cow encircled by the medical serpent with its tail in its mouth. Northcote was not a Morland at animals, for the beast is like nothing so much as the wretched horses which appear on Bank Holidays and attract the attention of the officers of the Society for the Prevention of Cruelty to Animals. Jenner is supported by his Quaker disciple Dimsdale, who combined the professions of inoculator-in-chief to the Russian Imperial family and Hertfordshire banker. His treatment was not least memorable for the gigantic fee of £12,000 and the pension of £500 which were bestowed by the grateful Czar. His miniature presents a face more than usually attractive, the pink cheeks harmonising well with the prosperity that naturally attaches to the idea of a Quaker banker.

Sir Hans Sloane, the proud possessor of a Dutch name, Scottish ancestry, and Irish birth, completed his cosmopolitan character with a foreign education before he settled in London. His portrait exhibits a man who was obviously successful. As he sits upon the chair of the President of the Royal Society, with the gilt mace supporting him upon the right, his dignity secured by an enormous Louis Quatorze wig, he fully looks the part of the impressive chairman. It must be confessed that his contributions to medical knowledge were not of the most valuable, but as long as the British Museum and London itself exist Sir Hans Sloane need not fear to be forgotten.

Richard Mead, though a Stepney man by birth, was also educated abroad at Leyden and Padua. He has won a right to a place here as fully as to his monument in Westminster Abbey. The portrait of the Court physician, to which office Mead soon attained, was naturally done by the Court painter, Allan Ramsay, and was very successful. Richard Mead himself, whose house, by-the-bye, stood in Great Ormond-street where is now the Hospital for Sick Children, and in whose hall till a few years ago out-patients used to wait, was a most excellent classical scholar and an enthusiastic collector of antiquities. This knowledge he employed in his endeavour to prove from the old medals and authorities that the status of the medical profession in the ancient world was much higher than is generally thought, and that its members were, as a class, wealthy and highly respected. The wealth he proved, but as to the respect paid it is to be feared that the honours of the contest remain with his opponent, the famous Conyers Middleton. There never was a physician in whom friends believed more fully, and one follower declared that he had saved the life of Queen Caroline when all the other medical men were poisoning her with their prescriptions. His neighbour and junior, Parsons, who occupied Red Lion-square, hardly deserves a place in the gallery, but perhaps he has arrived there chiefly because he "was cheerful and decent in his conversation," a character so rare in the eighteenth century that it may be held to excuse his presence. Of the picture all that need be said is that it bears out the reputation.

Curiously enough, the remaining three, who were all contemporaries, are more famous for their literary than for their scientific performances. Erasmus Darwin, John Wolcot (better known as Peter Pindar), and John Allen are the writers of works which are at least more remarkable than their surgical or medical skill. True that more men probably have read the Anti-Jacobin parody, the "Loves of the Triangles," than the original "Loves of the Plants," but we may still claim the latter as the honour of the profession. Darwin, like his greater grandson, was a product of Cambridge scientific training, and though the combination of science and poetry has not, since the days of Lucretius, been generally satisfactory, there can be no question of his right to a place among the prominent men of his day. Wolcot was a man of very different type. First a physician, then an ordained clergyman, and finally a professional satirist, he played many parts, though it was only in the last that he won success. His miniature, painted on ivory by Lethbridge, is more typical a portrait than the larger face, but in both are finely developed the cynical nose and mouth, which betray his mental attitude and explain the terror he inspired into that favourite object of his jibes, the farmer king. He has at least the honour of rendering the story of the monarch's puzzle over the dumplings and the pastry a historic commonplace, and he gives a picture of George III. which, if not exactly fair, is at least lifelike. He spared his professional brethren as little as his king, and not even the dignity of the President of the Royal Society saved Sir Joseph Banks from most unprofessional ridicule. Dr. John Allen, if less brilliant, was at least more attractive. He will be remembered best as the resident physician of Holland House, where he had to endure the caprices of his charming but unmannered hostess Lady Holland, who treated him in public almost as a servant. Everyone remembers the remark quoted in the "Life and Letters of Lord Macaulay": "Mr. Allen, there is not enough turtle to go round; you must have gravy soup or none." His portrait is a very attractive Landseer and presents an ideal Mr. Pickwick, with a bland benevolence that ought to have been sufficient to disarm all impoliteness. His fame as a comparative anatomist has been somewhat dimmed, and it may be that he will be best remembered by his history of "The Rise and Growth of the Royal Prerogative in England," which treated the subject in the most strictly orthodox Whig manner, as was to be expected from such a companionship.

It is harder to discuss the portraits of this century, which time has not yet ranked in order of importance. Amongst these is Guthrie, the daring and brilliant surgeon whose name will always be associated with the Peninsular War. In the Arctic room, again, which always has its group of spectators bearing witness to the curious fascination of the North Pole for the strain of Viking blood within us, is the portrait of Walker, the surgeon of the *Fox* which made the last sad discoveries of the Franklin expedition. Not far from the Watts portrait of Sir Andrew Clark is a fine full-length portrait of Sir Richard Owen, who, in his long life, had seen

Digitized by Google

greater developments in his profession than any of his predecessors.

One thing at least our profession may claim. Not one of its members hangs there as an awful example. For a chamber of horrors the law has an excellent candidate in Jeffreys and perhaps in Impey, the Church could spare Dodds, and literature might conveniently hang Godwin and Churchill in a rogues' gallery. As for the politicians, there are few who would obtain a unanimous vote of confidence, but the medical men's portraits, even including Peter Pindar's, are of gentlemen.

THE EFFECT OF BORAX ON THE CURDLING OF MILK.

BY F. J. ALLEN, M.A., M.D. CANTAB.,
PROFESSOR OF PHYSIOLOGY IN MASON COLLEGE, BIRMINGHAM.

ONE of the effects of adding borax to milk is to render it incapable of curdling, but the curdling property is restored on the addition of a small quantity of calcium chloride. I have frequently observed this condition in commercial samples of milk. Having made a number of laboratory experiments for the purpose of ascertaining the quantity of borax necessary to prevent curdling, I find as a result: (1) that milk containing one-tenth of its volume of cold saturated solution of borax is incapable of curdling with rennet (this is equivalent to about 36 grains borax to 1 pint milk)—smaller quantities of borax delay the curdling more or less; (2) that the addition of calcium chloride either before or after the rennet restores the normal curdling power; and (3) that boric acid added to milk does not delay curdling with rennet, but rather hastens it. The effect of boric acid seemed to indicate that the loss of curdling property in presence of borax was not due to the boric portion of the salt, but rather to its soda. I therefore tried the effect of adding sodium bicarbonate to milk. The results were as follows:—1. Curdling with rennet is prevented by adding to the milk one-sixth of its volume of a 5 per cent. solution of sodium bicarbonate. Smaller quantities retard curdling. 2. The addition of calcium chloride restores the curdling property apparently more quickly than in the case when borax has been used. From these experiments it appears that the prevention of curdling may be due to the removal of the lime salts from the field of action, but is more probably due to the formation of a soluble compound of the casein and alkali, which is decomposed by calcium chloride in excess. If borax removes calcium from the field of action it follows that not merely the curdling function will suffer, but also many other functions of the body in which calcium is needed. And even if the alkali of the borax is the only restrainer of curdling it is not desirable to neutralise the gastric juice by its use. Moreover, the presence of borax may prevent the normal production of acids by fermentation and thereby further hinder digestion.

Birmingham.

THE INTERNATIONAL CONGRESS OF DERMATOLOGY.

THE programme of the Third International Congress of Dermatology, to be held in the Examination Hall of the Royal Colleges of Physicians and Surgeons, Victoria Embankment, from Aug. 4th to Aug. 8th, has just been issued, and some interesting discussions are promised.

Mr. Jonathan Hutchinson, the President of the Congress, will be supported by the following Vice-Presidents: Dr. Wilks, President of the Royal College of Physicians of London; Mr. Christopher Heath, President of the Royal College of Surgeons of England; Dr. Walter G. Smith, President of the Royal College of Physicians of Ireland; Sir W. Thornley Stoker, President of the Royal College of Surgeons in Ireland; Dr. W. T. Gairdner, President of the Royal College of Physicians of Edinburgh; Dr. J. Struthers, President of the Royal College of Surgeons of Edinburgh; Sir J. Nicholas Dick, K.C.B., Director-General of the Medical Department of the Navy; Sir W. A. Mackinnon, K.C.B., late Director-General of the Medical Department of the Army; Sir William H. Broadbent, Bart.; Sir Joseph Lister, Bart., President of the Royal Society; Sir James Paget, Bart.; Sir Richard Quain, Bart.; Sir J. Russell Reynolds, Bart.; Sir Dyce Duckworth, Sir William MacCormac, Sir Douglas Maclagan, Sir Edward Sieveking, Dr. McCall Anderson, Dr. Mitchell Bruce, Dr. John Cavafy, Mr. Alfred Cooper, Dr. G. F. Duffey, Dr. J. F. Goodhart, Dr. Hughlings Jackson, Dr. Allan Jamieson, Dr. Robert Liveing, Dr. Payne, Dr. Douglas Powell, Dr. Pye-Smith, Dr. Hermann Weber; also Dr. Besnier, Professor Fournier, and Dr. Hallopeau, of Paris; Professor Leloir of Lille; Professor Lewin, Professor Köbner, and Professor Lassar of Berlin; Professor Neisser of Breslau; Dr. Unna of Hamburg; Dr. Veiel of Cannstadt; Professor Kaposi, Professor Neumann, Professor Lang, and Dr. Hans von Hebra of Vienna; Professor Schwimmer of Budapest; Professor Pick and Professor Janovsky of Prague; Professor Jarisch of Gratz; Professor Petersen and Professor Tarnovski of St. Petersburg; Professor Pospelow of Moscow; Professor de Amicis of Naples; Professor Pellizari of Florence; Professor Campana of Rome; Professor Boeck of Christiania; Dr. Welander of Stockholm; Professor Haslund of Copenhagen; Professor Castelo and Professor Olavide of Madrid; Professor Petrini de Galatz and Professor Kalindero of Bucharest; Zambaco Pacha; Professor Joannu of Athens; Dr. Duhring of Philadelphia; Dr. White of Boston; Dr. Nevins Hyde of Chicago; Dr. Bulkley, Dr. Keyes, and Dr. Fox, of New York; Dr. F. Shepherd of Montreal; and Dr. Graham of Toronto.

On the first day of the meeting after the preliminary business of the Congress has been dealt with Mr. Jonathan Hutchinson will deliver the presidential address, and the subject of Prurigo will be discussed by Dr. Besnier of Paris, Professor Kaposi of Vienna, Dr. J. C. White of Boston, and Dr. Payne of London. On Wednesday, Aug. 5th, the subjects for discussion will be the Etiology and Varieties of Keratosis and Syphilitic Re-infection; on Thursday, Aug. 6th, the Connexion of Tuberculosis with Diseases of the Skin other than Lupus Vulgaris, the Duration of the Period of Contagion of Syphilis, and Ringworm and the Trichophytons; and on Friday, Aug. 7th, the Nature and Relation of the Erythema Multiforme Group and Malignant Syphilis. Clinical demonstrations of cases will be given on Aug. 5th, 6th, and 7th, and various papers will be read during the progress of the Congress. Saturday, Aug. 8th, will be devoted to the clinical demonstration of cases, to be followed by papers.

Full information regarding the Congress can be obtained from the Secretary-General, Dr. J. J. Pringle, 23, Lower Seymour-street, London, W.

CHOLERA IN EGYPT.

THE manifestations of epidemic cholera which have appeared this year in Egypt have commenced earlier than in the epidemic of 1883 in that country, which began first of all at Damietta about the middle of June and lasted to September, and gave rise to a total mortality of over 25,000. Damietta, Alexandria, Chibin-el-Kon, and Cairo were the places most affected on that occasion. At the time of that outbreak there was no special activity of the disease in Arabia. There must always be some doubt as to the exact place and date of origin of an outbreak, but some sporadic cases of the disease seem to have appeared on the present occasion in Alexandria in March last. In the following month there were almost daily cases of cholera, and by the first three weeks of April these amounted altogether to 45 with 42 deaths. A few cases occurred in Cairo soon after the appearance of the disease in Alexandria. The disease has very slowly but steadily increased in Cairo. This outbreak in Egypt gave rise to a considerable exodus of the well-to-do classes, many of whom, it is understood, went to Marseilles. Two cases occurred in the 14th Soudanese Battalion at Tourah, where there is a large convict establishment. The disease has hitherto been very severe and fatal, some 80 or 90 per cent. of those attacked having died. On May 20th there were several fatal cases at Alexandria, at Cairo—in the old and new parts of the city—and some at Tourah-camp and other places. On the 22nd and 23rd there were 45 deaths from cholera at Alexandria and 75 at Cairo—mostly in old Cairo—and 8 at other places. On the 24th

Digitized by Google

there were 13 cholera deaths at Alexandria, 45 at Cairo, 15 at Tourah town, prison, and camp, and 9 deaths at other places. The total number of cases in Egypt at the present time is 115.

It does not appear that any cases have occurred among the British troops. Should it, unfortunately, happen that any of these are attacked the barracks will no doubt be forthwith evacuated and the troops moved out and encamped. The experience obtained in a former epidemic will not have been forgotten—viz., that the soldiers occupying an elevated site in the vicinity of Cairo had an immunity from the disease. One of the great things to be done in an epidemic is to select and occupy new and clean sites, to spread out the men as far as possible, and to have the freest ventilation. We have no doubt that even the movement of soldiers out of barracks in anticipation of, instead of after, an attack is occasionally the wisest course that can be adopted. The principal medical officer and medical staff in Egypt have, however, practical experience to guide them in dealing with epidemic cholera, and we may consequently feel every confidence in their judgment in this respect. The health of the British troops, however, continues to be excellent. The percentage of sick, including slight maladies, in the military hospitals on the 25th, according to telegraphic intelligence through Reuter's agency, was very low:—Cairo 6·06, Alexandria 4·81, Wady Halfa 4·83.

We wish that we could regard the sanitary state of Egypt generally, and of its towns in particular, as satisfactory as far as water-supply, drainage, and surface cleanliness are concerned. It is, after all, only during times of freedom from epidemics that the necessary work can be undertaken to prevent their occurrence, and it has been with a full knowledge of this fact that we have so constantly urged upon the Government of Egypt and of this country the grave importance of their duties and responsibilities in this respect. It will be a disgrace to our rule if we leave Egypt in the same unsanitary condition in which we found it. In finance, in the administration of law and justice to all classes alike, in education, and in promoting the greatest happiness of the greatest number England has done well in Egypt, but in sanitation and attempts at improving the public health little or nothing has been done up to the present time.

DEATH CERTIFICATION.

THE general meeting of the metropolitan counties branch of the British Medical Association was held on the 22nd inst., Sir William O. Priestley, M.P., presiding. The subject before the meeting was the improvement in the present procedure in death certification and registration, and from the report of the proceedings it is manifest that they took a very practical turn. Sir Henry Thompson moved the following resolution: "Considering that a Select Committee of the House of Commons has in 1893 made an extended inquiry into the subject of death certification and registration on the plan now followed in this country, and has reported that it manifestly fails to accomplish the purpose for which it was designed, this meeting is of opinion that Her Majesty's Government should be respectfully memorialised to bring in a Bill as soon as possible to give effect to an improved procedure in general accordance with the suggestions offered in the committee's report." Sir Henry Thompson passed on to observe that during the last twenty years or more the existence of grave defects in the system of death certification adopted in this country had not unfrequently been manifested, whether this system be regarded as a safeguard against criminal attempts on life or as a means of forming trustworthy records of disease for scientific purposes. He next referred to the fact placed before the Select Committee, that in 1892 no fewer than 15,000 cases of death occurred, in each of which no inquiry had been made into its cause and no certificate as to its cause had been forthcoming. This number of uncertified deaths formed a percentage of nearly three on the total number of deaths returned for the year. It also appeared that in 25,000 other deaths—a percentage of 4½—the cases were so inadequately certified as not to be classifiable, making together a class of 7½ per cent. in which no evidence of any value as to the cause of death existed. He suggested that they should forward a memorial to the Home Secretary with a request that he would consider the important work which had been already done by the Select Committee, and, if he saw fit, take steps to embody their recommendations in an Act of Parliament for the purpose of giving the country a greatly improved procedure in exchange for that at present employed.

In the absence of Dr. Farquharson, M.P., Dr. Isambard Owen seconded the resolution, and asserted that the State now winked at an exceedingly loose system of death certification, since under the present procedure it was possible for a medical man to give a death certificate on a patient whom he might not have seen for an interval of several weeks and perhaps months. The resolution was supported by Mr. Nelson Hardy, Dr. Alderson, Dr. Hugh Woods, and others, and was unanimously adopted. It is greatly to be hoped that other meetings may be held to discuss this very important subject, the resolutions adopted being forwarded to the local representatives in the House of Commons. While fully admitting the desirability of reform in our registration system, we would urge all members of the profession to avoid the somewhat pessimistic views adopted by the speakers at the Metropolitan Counties Branch. For is it justified by facts? Granting the 7½ per cent. of uncertified or badly certified deaths, and allowing 5½ per cent. for deaths certified by coroners, this makes 13 per cent., leaving 87 per cent. of the total deaths which may be assumed to be properly certified, and it must also be remembered that a proportion of deaths, by no means small, which the Registrar-General classifies as uncertified have been certified (in a fashion) by coroners after an informal inquiry. It is, therefore, most desirable that in criticising our death registration system it should be borne in mind that of the total number of deaths the large proportion of 87 per cent. are registered with a fair approximation to accuracy. Before, therefore, applying the legislative screw it will be well carefully to consider the present system so as to see where the defects are, and, this being ascertained, what are the reforms which should be made. The existing system has been in force in England and Wales for nearly sixty years, while death certification has been compulsory for twenty-two years. The deaths number in round numbers 550,000, being influenced by the presence or absence of epidemics, &c. As we have seen, with the exception of the percentage of thirteen no fault is apparently to be found, and this accords with every-day experience. In an overwhelming proportion of deaths the deceased is attended in the last illness by a registered medical practitioner, who gives a certificate of its cause (the correctness of which is not disputed) to a relative or friend. The death is registered, a burial order is given, and the body is buried. In cases where an inquest is held the coroner sends the cause of death as given by the jury to the registrar. The principal charges suggested by the Select Committee are that the body of a deceased person should not be disposed of either by burial or cremation without the certificate of a registered medical practitioner or of a coroner after inquest. This would imply that all informal inquiries by coroners are in future to be dispensed with. It is also recommended as a consequence of this that there should be appointed in every district a medical certifier to inquire into every uncertified death. The certificate of death is to be sent to the registrar direct and not to be given to the representatives of the deceased. The body is to be verified by the medical attendant, who is to be allowed a fee of half a crown for verification and certificate. That Medical attendance is to mean two visits before death within a fixed period of days. These and other recommendations will have to be most carefully studied before they are adopted in England and Wales. These parts of the United Kingdom have been divided into registration and coroners' districts which are presumably convenient, and the present system has been in working for more than half a century. It is a very grave question whether the suggestion of medical certifiers is a practical or workable one, and it is certain that coroners would strongly resent any encroachment upon their functions. So also with regard to the suggestion that the certificate should be sent directly to the registrar a very little reflection will show that this is wholly impracticable. What is really required is that the Act of 1874 should be carried out in the spirit as well as in the letter by medical practitioners, who should never give a certificate in any case which is doubtful, referring all such to the coroner. The registrars should in turn not accept a certificate which

Digitized by Google

is doubtful. Coroners should improve their informal inquiries and should have power to remunerate the medical practitioner called in for making an inspection of the body. Medical certificates should be given to the informant in a sealed envelope addressed to the registrar. In short, the present system should be improved in those points which need improving. These are much to be preferred to changes which would completely dislocate the present machinery without any compensating advantages.

THE SOUDAN EXPEDITION.

NOTWITHSTANDING that the Egyptian troops under the training and leadership of English officers and non-commissioned officers have undergone a remarkable improvement, and that their marching powers and endurance are undoubted, it seems to be still doubtful in the minds of many whether they will prove reliable in action if fiercely attacked by brave and determined troops like the Arabs. The Soudanese black regiments are, no doubt, excellent, and have also proved steady and reliable in a fight, but Egyptian regiments are composed of material which has been subjected to slavery and oppression from the time of the Pharaohs up to nearly the present period. The Egyptian soldiers are fine men in point of physique, patient, hard-working, and, in a military sense, well-trained and disciplined, but it seems to be still the opinion that they will require to be well "stiffened" by European troops when the advance on Dongola takes place. Anyway, the troops—both British and Egyptian—appear to be in excellent health and fettle at the present time. The power of the Khalifa is not what it was, and there seems to be little doubt that there is a good deal of disaffection and dislike to the present rule and a growing belief in the desirability of a change. If the Dervishes could only feel that they were to be subjected to English and not to Egyptian rule things would probably soon assume a different aspect, for, whatever may be the case now, the Arabs, with their courage and manly qualities of character, once had a firm belief in the fairness and justice of the British.

As regards the hospital accommodation and arrangements at the different stations everything appears to be in a satisfactory state, and, considering the great heat, the dust-storms, the fatigue and monotonous life, and the difficulties in the way of provisioning the force, the low sick-rate shows that the sanitary and hygienic arrangements of the expeditionary force must be uncommonly good. Time is the most important element in expeditions of this nature. The less the time at disposal the greater the pressure, of course, on all concerned and especially on the medical, commissariat, and store departments of an army. Happily, in the present instance, there has been sufficient time available for making all the preparations and arrangements for the expedition in a satisfactory way. The hospital accommodation at Akasheh is composed of huts and is good and sufficient, and the same may be said of that at the other stations; the sick transport arrangements are also working satisfactorily. It may be added that, as far as the officers of the force are concerned, the work has been very hard. The Nile is believed to be now rising. The past week has been comparatively uneventful; there has been no fighting, the Anglo-Egyptian force being simply on the alert and attempting to perfect their preparations for the future advance.

THE EVELINA HOSPITAL FOR SICK CHILDREN.—The report of this hospital for the year ending Dec. 31st, 1895, is a very satisfactory document so far as the management of the institution is concerned, but, like a great many more charities at the present time, the hospital requires increased support from the benevolent public. During the past year 782 children have been treated in the hospital. The total number of deaths during the year was 163; of these 31 cases were admitted moribund (dying within forty-eight hours), and in 83 the children were under two years. In the out-patient department 802 minor operations and about 1000 dental operations have been performed. Five hundred and twenty accidents have been attended to, 42 cases being admitted to the wards; of these 20 were of a serious character.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Condition of the Borough of Pembroke, by Dr. R. J. REECE.—The borough of Pembroke, which includes Pembroke proper and Pembroke Dock, has the reverse of a satisfactory history and it has received seven visits from the medical department of the Local Government Board since 1878. The population has oscillated, but since 1871 it has undergone some steady increase until in 1891 it reached 14,978, and building operations are still in progress. In Pembroke proper the water-supply comes from a number of sources; these include local wells, both public and private, and they are in many instances open to the risk of pollution. One known as the Commons Well was condemned by Dr. Airy of the Local Government Board in 1879 and was referred to as a supply that should be closed, but in 1895 it was still in use. The wells in Pembroke Dock answer to much the same description and they cannot be regarded with any satisfaction in so far as wholesomeness and freedom from pollution are concerned. On the other hand, certain public supplies are available, and some further action has been attempted by the town council with the view of increasing the service from a tunnel driven into a hillside. The sewage outfalls from Pembroke are most imperfect. One, for example, is into a mill-pond connected with the Pembroke river; another is into the Commons Lake, a piece of marshy land through which a stream flows, and this stream is at times resorted to for a water-supply. The drains of Pembroke are very deficient, having originally been constructed of rubble to carry off surface water. At Pembroke Dock certain sewers have been constructed, but these are a cause of nuisance at their outfall, the sewage being deposited, for example, under wharves and on the foreshore. But the main part of Pembroke Dock is altogether unsewered. In the matter of house drainage, excrement disposal, &c., the sanitary administration of this borough also leaves much to be desired; but it is evident that the questions of water-supply and of sewerage are those to which the greatest importance attaches at the moment. Formal complaints have been addressed to the Local Government Board and to the town council in these matters, and it is impossible to dissociate Dr. Reece's recent visit and report from the action which the central department may determine to take as regards this borough. When Dr. Airy reported in 1879 he stated that the medical officer of health and the inspector of nuisances had kept the town council truthfully informed of the sanitary requirements of the district, but that the town council had a most imperfect realisation of their duty as a sanitary authority. With but trivial exception—the exception including the improvement of the Pembroke Dock water-supply—this statement is declared by Dr. Reece to be as true now as it was when it was penned seventeen years ago. The interests of the public as well as of the ordinary population are involved by reason of the Admiralty Dockyard, and it seems clear that some decided change of administration must now be insisted on in this antiquated and backward borough.

On the Prevalence of Enteric Fever in West Bromwich, by Dr. G. S. BUCHANAN.[1]—This report deals not only with a prevalence of enteric fever but it also enters with much detail into the sanitary conditions with which that disease has been associated. The population of the borough now exceeds 60,000, and for years past there has been excess of enteric fever. In 1890 the notified cases were 84, in 1893 they reached 91, and in the first ten and a half months of 1895 they were 112 in number. In seeking the causes of this occurrence Dr. Buchanan ascertained that there were many serious defects in the sanitary administration of the borough which can hardly fail to have had a distinct relation to the sustained prevalence of fever. This was especially the case with respect to the privy-middens and large ash-middens which prevail and which are definitely referred to as constituting a serious danger to the health of the inhabitants. The description given in the report as to this is about

Digitized by Google

as disagreeable reading as anything could be, and it really becomes a marvel how some of our large boroughs can in these days maintain such a system. It is altogether monstrous that a sanitary authority should not deal with the "semi-liquid, evil smelling" matter of excrement, slops, and all sorts of offensive filth which foul the air around the several groups of houses, and which are allowed to accumulate until either the inspector of nuisances or, failing him, some householder chooses to call attention to the existence of a nuisance. It is the whole system which is wrong, for the very construction of such midden-privies must necessarily involve a recurring nuisance and source of danger to health. Happily, wells have been got rid of as local supplies of water and other amendments have been carried out, but in some respects—as, for example, in the faultiness of its refuse removal—West Bromwich remains much as it did when reported on by Dr. Ballard in 1875. Every point bearing on the health and sanitation in the borough, including its milk-supply, is discussed with much care in the report, which is the first one which the Local Government Board have issued from the pen of Dr. G. S. Buchanan. As the record of a careful inquiry into the administrative aspects of a large borough which has suffered from preventable disease it is a most carefully compiled piece of work, and recalls the excellence of the early work of the writer's father, the late Sir George Buchanan.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Liverpool Port Sanitary District.—The jurisdiction of the Liverpool port sanitary authority extends over a very considerable area, reaching as it does from the south side of the River Ribble on the north, to the north side of the River Dee on the south, and embracing the waters of the Mersey to a point considerably eastward of the entrance to the Manchester Ship Canal. The staff of the authority consists of Dr. E. W. Hope, medical officer of health of Liverpool, an assistant medical officer, and three sanitary inspectors of shipping. The completion of the Manchester Ship Canal has had the effect of converting Manchester into a seaport town and several inland districts into riparian districts. Arrangements have accordingly been made whereby the Liverpool port sanitary authority deal with cases of infectious disease found on vessels passing through the Liverpool waters but bound for Manchester, while the sanitary supervision of vessels themselves is left to Manchester. During 1895 the inspectorial staff of the Liverpool port sanitary authority inspected 3153 vessels, and no less than 50 per cent. of them were found in one or another sense to be defective from a sanitary standpoint. Defects: Total number, 3154; average per vessel, 2. (*a*) Of construction, 678 = 21·4 per cent.; (*b*) structural, 963 = 30·6 per cent.; and (*c*) dirt, 1513 = 47·9 per cent. The above is taken from the report before us. During 1895 there were 63 cases of infectious disease taken from vessels arriving at Liverpool, as compared with the average for the previous ten years of 33·9. Among the cases of non-notifiable disease which came to the knowledge of the authorities there were, we note, three cases of Beri-beri. The figures of emigration for 1895 show an increase on those for 1894 of 11,049, but it must be remembered that owing to the restrictions placed upon emigration to the United States there was a very large diminution in numbers during 1894. Among the 117,196 emigrants, 91,805 were bound for the United States and 20,385 for Canada, the month during which most emigrants embarked being August. The emigrants are medically inspected by medical officers appointed by the Board of Trade, but one of the port sanitary inspectors is present at each of these inspections to take charge of any who may be rejected by the medical examiners. Amongst those rejected during 1895 we note that scabies and alcoholism were common, as also were varicella and measles.

Ipswich Urban Sanitary District.—The population of Ipswich is estimated to the middle of 1895 as 60,022; the birth-rate for the year in question was 31·1 per 1000 and the general death-rate 18·7. There were eighty-six cases of enteric fever notified in the borough during 1892, and of this number no less than thirty-one occurred in the parish of Stoke. The population of Stoke is not furnished in the report before us, but we gather from the 1891 census that at that time it was 4099, a fact that would seem to indicate that, even allowing for a considerable increase during the last quinquennium, about one-third of the total cases of enteric fever occurred among a twelfth of the population. Mr. George Elliston states that his annual report for 1891 contained an account of a serious outbreak of enteric fever in Stoke, and he now adds that the recurring outbreaks of the disease in that locality "show that the drainage is utterly bad and no improvement in the health of the district can be looked for until it is properly sewered." Surely the Ipswich Corporation should now take the matter in hand. In that part of his report relating to the port of Ipswich Mr. Elliston states that several complaints were made during the hot season of the nuisance in the river at the main outfall works, and additional screening of solid matter was undertaken. It is to be regretted that a beautiful estuary like the Orwell should be thus polluted, and it is surely time that a proper method of treatment should be adopted for the sewage of Ipswich. We are glad to note in regard to the sanitation of individual houses that during 1895 some 250 privy middens were converted into waterclosets. It is to be hoped that in the next annual report Mr. Elliston will be able to record the drainage of California and Stoke.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6284 births and 3775 deaths were registered during the week ending May 23rd. The annual rate of mortality in these towns, which had been 18·5 and 18·4 per 1000 in the two preceding weeks, further declined last week to 18·1. In London the rate was 17·8 per 1000, while it averaged 18·4 in the thirty-two provincial towns. The lowest rates in these towns were 12·4 in Bristol, 12·5 in Brighton and in Hull, 12·6 in Leicester, and 13·8 in Cardiff; the highest rates were 22·9 in Birmingham and in Manchester, 24·5 in Sunderland, 25·4 in Oldham, and 26·0 in Salford. The 3775 deaths included 590 which were referred to the principal zymotic diseases, against 622 and 561 in the two preceding weeks; of these, 214 resulted from measles, 186 from whooping-cough, 83 from diphtheria, 50 from diarrhœa, 31 from scarlet fever, 25 from "fever" (principally enteric), and 1 from small-pox. No fatal case of any of these diseases was recorded either in Plymouth or in Swansea; in the other towns they caused the lowest death-rates in Wolverhampton and Bradford, and the highest rates in West Ham, London, Salford, Oldham, and Sunderland. The greatest mortality from measles occurred in Hull, Birkenhead, Sunderland, Portsmouth, and Oldham; and from whooping-cough in Cardiff, Newcastle-upon-Tyne, Salford, Preston, and Sunderland. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 83 deaths from diphtheria included 56 in London, 7 in West Ham, 5 in Birmingham, and 3 in Leicester. One fatal case of small-pox was registered in Bristol, but not one in London or in any other of the thirty-three large towns. There were 22 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 23rd inst., against 13, 15, and 20 at the end of the three preceding weeks; 5 new cases were admitted during the week, against 3, 5, and 6 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2596, against 2523, 2527, and 2539 on the three preceding Saturdays; 305 new cases were admitted during the week, against 236, 238, and 293 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 260 and 249 in the two preceding weeks, further declined to 218 last week, and were 87 below the corrected average. The causes of 46, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Leeds, Hull, Newcastle-upon-Tyne, and in sixteen other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Birmingham, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18·9 and 19·3 per 1000 in the two preceding weeks, declined again to 19·2 during the week ending

Digitized by Google

May 23rd, but exceeded by 1·1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Perth and 15·0 in Paisley to 20·9 in Glasgow and 22·7 in Greenock. The 560 deaths in these towns included 29 which were referred to whooping-cough, 21 to measles, 18 to diarrhœa, 6 to "fever," 5 to scarlet fever, 3 to diphtheria, and not one to small-pox. In all, 82 deaths resulted from these principal zymotic diseases, against 76 and 69 in the two preceding weeks. These 82 deaths were equal to an annual rate of 2·8 per 1000, which corresponded with the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 30 and 25 in the two preceding weeks, rose again to 29 last week, of which 25 occurred in Glasgow, 2 in Aberdeen, and 2 in Paisley. The deaths from measles, which had been 11 in each of the two preceding weeks, rose again to 21 last week, and included 18 in Glasgow and 2 in Dundee. The deaths referred to different forms of "fever," which had been 4, 9, and 14 in the three preceding weeks, declined again to 6 last week, of which 5 occurred in Glasgow, where the 5 fatal cases of scarlet fever were also recorded. The 3 deaths from diphtheria corresponded with the number in the preceding week, and included 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 88 and 110 in the two preceding weeks, were 109 last week, and slightly exceeded the number in the corresponding week of last year. The causes of 38, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·9 and 22·8 per 1000 in the two preceding weeks, further rose to 23·7 during the week ending May 23rd. During the past eight weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 18·6 in London and 17·7 in Edinburgh. The 159 deaths registered in Dublin during the week under notice showed an increase of 6 upon the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 13 and 5 in the two preceding weeks; of these, 3 resulted from whooping-cough, 3 from "fever," 1 from small-pox, 1 from scarlet fever, and 1 from diarrhœa. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 3·5 in London and 0·9 in Edinburgh. The 3 fatal cases of whooping-cough exceeded the number in any recent week. The deaths referred to different forms of "fever," which had been 7 and 0 in the two preceding weeks, were 3 last week. The mortality from scarlet fever corresponded with that recorded in the previous week, and the fatal case of small-pox was the first registered within the city during the past six weeks. The 159 deaths in Dublin last week included 22 of infants under one year of age, and 31 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers in the preceding week. Eight inquest cases and 7 deaths from violence were registered; and 68, or more than a third, of the deaths occurred in public institutions. The causes of 7, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-MAJOR SIMPSON has embarked for South Africa and Surgeon-Captain Perry has been appointed to succeed him at the Royal Arsenal, Woolwich. Surgeon-Captain Jevers has been appointed to the Medical Charge at Dorchester and Surgeon-Captain Cummins to Hounslow. Surgeon-Captain Lavie has arrived in Egypt. Surgeon-Captain Burke has embarked for the West Coast of Africa and the arrival there of Surgeon-Captains Hosie and Josling is reported. Surgeon-Captain Browne has been transferred from Buttevant to Cork.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel Robert Blood, M.D., has been appointed Brigade-Surgeon-Lieutenant-Colonel, vice J. P. H. Bolleau, M.D., F.R.C.S.I., retired.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant-Colonel P. A. Weir (Bengal) is appointed to officiate as Residency Surgeon in the Western Rajputana States, with effect from the date of assuming charge and during the absence on furlough of Surgeon-Lieutenant-Colonel A. Adams, or until further orders. Surgeon-Captain P. J. Lumsden, Residency Surgeon in the Persian Gulf, is appointed to officiate as Medical Officer of the Deoli Irregular Force and of the Haraoti and Tonk Political Agency, with effect from the date of assuming charge, vice Surgeon-Lieutenant-Colonel P. A. Weir, M.B., and during such time as Surgeon-Captain H. R. Woolbert, M.B., may officiate as Residency Surgeon in Mewar, or until further orders. Surgeon-Major F. F. Perry, Professor of Surgery, Lahore Medical College, is appointed to officiate as Principal of that College, in addition to his own duties, during the absence on leave of Surgeon-Lieutenant-Colonel S. H. Browne, or until further orders. Brigade-Surgeon-Lieutenant-Colonel Robert Jameson, Deputy Sanitary Commissioner, North-West Provinces and Oudh, retires from the service.

NAVAL MEDICAL SERVICE.

Inspector-General of Hospitals and Fleets Adam Brunton Messer, M.D., has been placed on the Retired List.

The following appointments are announced:—Surgeons: J. C. Ferguson, B.A., M.B., to the *Herald;* H. E. South to the *Victory*, additional for the *Duke of Wellington;* W. H. S. Stalkart, M.D., to the *Mosquito;* and A. S. Nance to the *Edinburgh*.

THE LATE ASHANTI EXPEDITION.

The late Ashanti expedition seems likely to be productive of great benefit in many directions. There is every reason to hope that an end will be put to the frequent raids and incursions of the Ashantis into the districts in their vicinity, that a great check has been imposed upon slavery, and that the downfall of Prempeh will be followed by the total prohibition of human sacrifices and other cruelties. The political and commercial consequences of the expedition will likewise be considerable. Let us hope, now that we have a dominating control over that part of the country, that attempts will be made to improve the sanitary condition of the stations occupied by us. The loss of life on the West Coast of Africa from fever and climatic disease is terrible. Numbers of young men go out from this country to that part of Africa only to die there or to return invalided to England with their health and strength wrecked and shattered. A very careful inspection of the districts occupied by Europeans should be made with a view to the total abandonment of the most unhealthy and the selection of the best stations that can be found; and attempts should be made to drain the soil, to harden and cleanse its surface, to make roads, and to clear away superfluous vegetation. Proper habitations, well raised above the soil, should also be provided.

DEATH IN THE SERVICES.

Deputy-Inspector-General R. J. Sweetnam, R.N. (retired), at Mount Pleasant, Dawlish, on the 20th inst., aged fifty-three. He joined the Navy as a surgeon in February, 1864, and in the following year was present at the action of Ikorudu, in the Lagos Lagoons. For his services in attending the wounded on the field on this occasion he was mentioned in despatches, and received the thanks of the Secretary of State for War. He was in medical charge of the Niger expeditions 1864–66 and was the author of the "Rules and Regulations for Preserving the Health of Ships' Companies in Lagos Lagoons and the Niger," which have been embodied in the North-East Africa "Station Order-book."

THE ROYAL CAMBRIDGE ASYLUM FOR SOLDIERS' WIDOWS.

Lord Wolseley presided on Tuesday last at the forty-fifth annual general court of this institution, when it was announced that there were sixty-six widows in the asylum each receiving 7*s.* a week and a coal allowance. A new system of nursing the aged and infirm had been inaugurated, but owing to want of funds there would be no election of inmates this year. The receipts for the year amounted to £3000 and payments to £4000, £1399 of which had been invested.

ROYAL MILITARY TOURNAMENT.

The Royal Military Tournament opened yesterday at the

Digitized by Google

Agricultural Hall, Islington. Surgeon-Major Alexander of the Coldstream Guards, the medical officer in charge of the troops, is assisted by Surgeon-Major Lawless, A.M.R., and Surgeon-Lieutenant Kenneth Cameron, A.M.S.

H.R.H. the Princess Louise will open the new Headquarters of the London Companies Volunteer Medical Staff Corps, Calthorp-street, and distribute ambulance prizes on on Wednesday, June 10th.

"Audi alteram partem."

MEDICAL CERTIFICATES AND PUBLIC ELEMENTARY SCHOOLS.

To the Editors of THE LANCET.

SIRS,—In connexion with the remarks in your issue of this week on the subject of Medical Certificates and Public Elementary Schools will you allow me to call attention to a recent departure in the practice of the Education Department which, if followed out and insisted upon, is certain to do much harm by impeding some of the most obvious and important steps which should be immediately taken in connexion with incipient epidemics of infectious disease amongst school children in rural districts? I use the term "fresh departure" advisedly, because there happens to be a larger number of separate public elementary schools in the extensive area for which I act as executive medical officer of health than in the case of any other medical officer of health in England and I am almost daily called upon to give certificates of some kind or other in connexion with public schools, but it is only on one or two very recent occasions that I have met with a demand for such a certificate as is referred to below. All medical officers who have had much experience in rural districts in the etiological investigation of epidemics of such diseases as diphtheria, scarlet fever, whooping-cough, and measles will agree with me that in sparsely populated districts the public school is as a rule the predominant source of infection and that in the majority of cases the dissemination takes place through mild and medically unattended cases affected so slightly as not to attract serious attention even from their parents and who either attend school personally or, if remaining at home with what is called (and often generally believed to be) merely "a cold," their brothers and sisters continue to attend school.

Medical attendance is less accessible and of necessity much more frequently done without by the working classes in rural districts than in urban districts, so that a large proportion of cases escape notification and often, after a few days' illness with "a cold and a bit of a rash or of sore-throat," children are sent back to school in response to the customary printed form of notice either to send the child or a medical certificate. Often and often when remonstrating with parents for sending children to school whom, although not medically attended, they must have known were suffering from a prevailing epidemic, I have been met with the production of the formal printed notice to send the child, also with the remarks by the mother that "the child was not bad enough to need a medical man and they were afraid of being summoned, and they thought if any harm did come through the child going to school they would not be to blame after receiving such a notice." It is in such cases as these that the cordial coöperation of a zealous and intelligent school teacher is of the utmost assistance to sanitary officials in carefully excluding all justifiably suspicious cases and all children from families where there is reason to believe any are ill with the prevailing complaint, although no medical man is in attendance. Such assistance school teachers are as a rule most anxious to afford, but their hands are already, as it is, very much tied by the regulations requiring the child's attendance or a medical certificate; but if the new departure of the Education Department is enforced they will be very much more tied, as this requires that, on counting up the number of attendances made by a child in the calculation of the daily average attendance of a school for the purpose of the grant in aid, before any allowance can be made for absence through illness under the 101st article of the code it must be shown that the child had been excluded by a special order of the sanitary authority referring separately to each child, and stating beforehand the date at which the exclusion was to commence and when it was to cease. This article in the code is not new, but the practical application of it in the way referred to in this letter is new, at least in my experience, and constitutes the new departure in practice to which I wish to direct attention.

As I write this I have before me an official letter from the Education Department in which it is stated, in reference to a number of children who had been most properly excluded from school during an epidemic of scarlet fever—either because a brother or sister was notified as suffering from scarlet fever, or some children in a house were with good reason suspected of being similarly affected but with ill-defined and exceedingly mild symptoms and medically unattended, or for some other good reason on my advice as medical officer of health—that the Education Department decline to make any allowance unless it can be shown that the children were so excluded by a previous special order of the sanitary authority. Considering that to be of any service exclusion should be immediate and that as a rule sanitary authorities meet, as in the present instance, once a month only, the absurdity is too patent to merit comment. That the term "sanitary authority" is here used by the Education Department in its technical and legal sense—viz., as the sanitary council of the department—is obvious from a reference to Clauses 88 and 101 in the 1896 Education Code. Even assuming each sanitary authority to have power to transfer its responsibility in such cases to the medical officer of health, his visiting, diagnosing, and writing orders in each individual case will involve very injurious delay, to say nothing of an enormous number of immediate and often unnecessary visits and certainly in many cases a very undesirable clashing with private medical practitioners. In a similar case which came under my notice a few weeks ago and in which the orders for exclusion were similarly demanded by the Education Department if any allowance was to be made, the epidemic had been one of whooping-cough and only a few of the most severe cases had been medically attended. The schoolmaster had simply used his common sense and good judgment to exclude children coming from houses in which it was a matter of notoriety and an admitted fact that the children were suffering from whooping-cough.

Such unnecessary and impracticable regulations tend to restrict personal discretion and to check the salutary zeal for the prevention of disease with which school teachers are often imbued.

I am, Sirs, yours faithfully,

W. N. THURSFIELD, M.D. Edin.,
Medical Officer of Health for a number of Sanitary Districts in Shropshire and Seven Adjacent Counties.

Shrewsbury, May 23rd, 1896.

"REGISTRATION OF MIDWIVES."

To the Editors of THE LANCET.

SIRS,—I desire to thank you for your kind and appreciative notice of my labours in connexion with this unhappy and unfortunate midwifery business.

Your wise remarks as to the necessity which exists, in view of any practical legislation, of greatly simplifying suggestions in connexion with this subject are well timed, and will I hope be taken to heart by the Midwives Institute and its supporters. Not only are the geese of these people all swans, but their very ducks belong to the same species. The importation by them of so exalted a body as the Privy Council into the administration of what after all is a very humble matter, is a good example of unconscious humour and also of the fact mentioned. It reminds me of the case of the governor of a certain German castle, who was severely taken to task for having omitted to fire a Royal salute upon a necessary occasion. The poor governor gave the following reasons for his apparent neglect of duty: (1) that he had no proper artillerymen, (2) that his powder was bad, and (3) that there was not such a thing as a cannon on the premises. The last reason might have sufficed and been fairly conclusive. The Midwives Institute and its supporters have apparently plenty of cannon, although perhaps, after all, they are not very big guns and are more suitable for firing salutes than for practical warfare. They will, no doubt, learn in time that by using a simple musket they would be

Digitized by Google

able to shoot with much greater accuracy and precision and with infinitely better results.

I am not sure that the suggested creation of an expensive and complicated system of midwives boards stands in much better case than the suggestion anent the Privy Council. It is invariably a wise thing to resist the beginnings of evil, and the absence of these boards would greatly tend to promote simplicity and economy in dealing practically with this question. I certainly regard them as more ornamental than useful. It is in this connexion a very remarkable fact that, while we have heard on all hands of the great things which have been done in other countries in connexion with the registration of midwives—the Austrian Minister of the Interior and the regulations issued by him have been, for example, a perfect Godsend to the council of the Lancashire and Cheshire Branch of the British Medical Association in connexion with their Bill—it never apparently occurred to any of these Bill promoters that the Local Government Board is the Ministry of the Interior in these islands and that its medical department is in the highest degree qualified to deal with certain aspects of the present question. All sanitary details should, for example, be left absolutely to its discretion, so that they might be varied from time to time as the progress of knowledge and altered circumstances might dictate. A "complication" of labour within the meaning of the Act would not, of course, be a varying quantity and should be definitely stated in the Act itself. How natural also in this connexion it would be to avail ourselves of the complete network of sanitary administration spread over the country. The local medical officer of health, having received his instructions from the Local Government Board, would annually issue to the midwifery nurses upon his register a copy of the sanitary precautions they must take and a list of "complications" the presence of which would demand medical assistance. In this way two desirable objects would be attained: (1) the nurses would be annually reminded of their duty in these respects; and (2) they would be kept in touch with the local administration.

The General Medical Council, having already many duties to perform, is naturally very shy about being too closely connected with any Act for registering midwives, but I am afraid that in any Act which would in any measure do justice to our profession some action on the part of the General Medical Council is absolutely indispensable. Its duties, however, need not be very onerous and would be mainly three: 1. To formulate rules for the guidance of members of the profession engaged in the training of midwifery nurses and to see that they were observed. In this way the midwife manufacturing business would be brought within the limits of what was reasonable and necessary, and the advantages to be derived from being a registered medical student and pupil midwife would again become more real and less problematical. 2. To increase from time to time the six months' minimum training, if necessary and desirable. 3. To nominate examiners and institute examinations should they be found necessary, which, in my opinion, they are not. Under any system of registration the training of these women will form a humble but integral part of the medical education of the country, and the General Medical Council certainly is the proper authority to deal with the matter, although there is no reason why the examinations should be either elaborate or costly. Their absence would certainly simplify matters, although there is no apparent reason why, if instituted in the way suggested and not made too numerous they should not pay for themselves. I attach, however, no great value to these suggested examinations and regard the training as the one question of primary importance; it is, perhaps, needless to say that the present system should, as far as possible, be carefully avoided. To inflict upon these very partially educated women learned and long-winded harangues upon the science and art of midwifery seems to me a proceeding of very questionable taste and utility. The aim of any real training should rather be to drill into these women day after day, not only by precept but also by example, the infinite importance of cleanliness, of patience, and of kindly consideration in the discharge of their duties, and to endeavour as far as possible to make them masters of the practical management and hygiene of a normal case of labour and of the nursing details essential to the comfort and welfare of every parturient woman. It is neither necessary nor desirable that these women should aspire to be amateur doctors or even specialists in their own department, although no doubt some advances have already been made in this direction. "You are suffering from inflammation of the overtures" said one of these highly educated and diplomatised ladies recently to a confiding client. I dare say the poor client believed her; but our profession will no doubt be well advised in very politely declining any "overtures" of that description. The educational overture should be set to an entirely different tune. It might further be quite fairly urged against the necessity for any examination that the majority of the candidates in midwifery nursing who might afterwards undertake the duties of a midwife would probably be young and middle-aged widows of moderate education and good moral character who had been to some extent sobered by the cares of life and who would have many powerful incentives to diligence and care during the period of their training. The proposed midwifery nurse, then, having received such a training as I have indicated and having the medical officer of health to supervise her on the one hand and the medical practitioner to assist her when necessary upon the other, would be fairly launched upon the sea of life. Would the legal creation and recognition of such a woman be detrimental to the welfare of our profession? I cannot suppose that it would. It is, at least to me, quite obvious that the profession would do well to consider the facts connected with this subject wisely, lest they should be considered and dealt with in a manner which might prove very unwise. I have, however, no doubt that in dealing even with this thorny subject the profession will prove itself worthy of its traditions, neither forgetting what are its just and lawful rights nor wrapping itself up in an impenetrable cloak of ignoble selfishness, but that in this as in all things it will remember those higher claims of humanity to which it has never turned a deaf or an indifferent ear. "To do justly, and to love mercy" should be the aim of every one of us.

I am, Sirs, yours truly,

Salford, May 27th, 1896. WM. FRASER.

A DECEPTIVE ETHER INHALER.

To the Editors of THE LANCET.

SIRS,—I remember some years ago hearing of a case in which a patient was anæsthetised with a Clover's inhaler pure and simple. When the operation had been successfully concluded it was discovered that the ether bottle had never been opened, and that the only anæsthetic used had been the carbonic acid manufactured by the patient himself. I have recently had a somewhat similar experience which is, I think, worthy of record. I had occasion to anæsthetise a lad aged fifteen years in order to reduce a dislocation of the patella. As I was working single-handed I naturally preferred to give ether, and I used for the purpose a Clover's inhaler which had not been used before since it reached me from the maker. Having poured in a measure of ether I began the administration with the indicator at "0," and gradually rotated the box until after about two minutes the pointer stood at "Full." The patient did not cough at all and struggled very little. By the time the indicator was at "Full" he had passed into a condition of partial anæsthesia and in this state he continued for some minutes. Muscular relaxation was not complete and the corneal reflex was not abolished, but cyanosis was so marked that I did not think it wise to carry out the rule I learned from Dr. Hewitt, to keep the inhaler closely applied until the breathing became stertorous, and only then to begin to allow the patient an occasional breath of fresh air. Owing to the cyanosis, though stertor was not present and the pupils had not begun to dilate, I removed the inhaler for a breath after every eight or ten breaths. It was quite apparent that the patient was not getting enough ether to anæsthetise him fully, and as the room was rather cold I thought that defective evaporation might account for it. I therefore applied hot sponges to the box of the inhaler, but the patient's condition remained unchanged. Twice I laid aside the inhaler for a moment and endeavoured to reduce the dislocation, but each time I found that muscular relaxation was not complete, and that the patient (who was otherwise quiet) resisted my manipulations. Finally, after about ten minutes, during all of which time the indicator was at "Full" and the patient had only an occasional breath of fresh air, I gave up the ether in despair, administered chloroform to complete anæsthesia, and reduced the dislocation without

Digitized by Google

difficulty. When I came to examine the vitals of the ether inhaler the mystery was cleared up. The marks on the box were liars; when the indicator was at "0" the patient was receiving the full blast of ether, and when it was at "Full" he was receiving back from the bag nothing more than his own breath. But this was not simply the fault of the engraver, for the "0" is where it is usually placed in the instrument made by Messrs. ——, beneath the side-tube through which the ether is poured into the box. The inhaler itself is at fault—a case of "transposed viscera." The inhaler was made by one of the best-known firms in London. I am not desirous of publishing the name of the makers, for this incident has not shaken my confidence in the quality of their goods; but I shall write privately to inform them of the practical joke they have played on me. Perhaps the most remarkable fact about the whole experience is that the patient did not cough at the outset of the administration, when, with the index at "0," he was receiving the full blast of ether. I have since tried it myself and find the effect of this strength of ether vapour on a membrane not yet dulled by commencing anæsthesia extremely irritating. I am, Sirs, yours truly,

Nagasaki, Japan, Feb. 6th, 1896. MAURICE EDEN PAUL.

EUPHORBIUM AS A CAUSTIC.

To the Editors of THE LANCET.

SIRS,—The following particulars may be of interest to some of your readers. I was staying in the country in Normandy last year and was asked one day, in an unofficial way, what was a good thing for "warts." The mention of the different 'folk," magical, and cabalistic methods led to a general discussion of the subject, and at last the proprietor of the hotel related the case of a child who had been treated for months without any benefit by the leading skin specialists for innumerable warts on the face, and who had been cured in a few days by a local sorceress. The remedy used was the fresh milky juice from the stems of the common garden euphorbium, a weed that is plentiful in those parts. It so happened that one of the kitchenmaids at the hotel had recently developed a crop of warts on the hands and she very willingly consented to become the subject of an experiment, which was entirely successful. The application of the juice leads to the formation of a blister under the wart, which falls off in due time. According to Dorvault, a French text-book on pharmacy, exotic euphorbium enters into the composition of an "everlasting blister" into some topical applications for cancer in veterinary remedies, and the 'Aveloz nült," a cancer specialty, consists also of it. The dried gum resin requires the greatest caution in manipulation on account of the irritating nature of the powder. Folkard[1] says that a variety is cultivated in India as a sacred plant, prayers being addressed and hogs sacrificed to it.

I am, Sirs, yours faithfully,

Rue Vernet, Paris, May 14th, 1896. OSCAR JENNINGS.

PIG *v.* OX BILE TABLOIDS IN JAUNDICE.

To the Editors of THE LANCET.

SIRS,—As success in treatment sometimes depends more on the kind and mode of preparation of the remedy employed than anything else, from having noticed the remarks in the Laboratory Record of THE LANCET of May 16th on the advantages of coating bile tabloids with keratin to enable them to pass through the stomach undissolved into the intestines, where alone they are of therapeutic value in cases of jaundice, I desire to supplement those judicious remarks by what appears to me would be a useful hint to manufacturing pharmacians from a therapeutic point of view, and that is to employ in their preparation pig's instead of ox bile, for the important reason I pointed out in a work on the various forms and treatments of jaundice some thirty years ago, that from the ox being a herbivorous animal its bile is but ill suited for the purposes it is intended in a flesh-eating animal such as man is; whereas the pig being omnivorous like the human being, its bile contains exactly the ingredients necessary to supply the place of those that are absent from the digestive canal in cases of jaundice in the human being, which ox bile does not. Why, then, one naturally asks, should our pharmacians put ox bile into their tabloids when it is quite as easy for them to obtain and use pig's bile—seeing that the object in view in prescribing another animal's bile is to prevent the patient from emaciating and dying from inanition in consequence of his food not being properly digested and prepared in the intestinal canal for the purposes of absorption and assimilation? For if the food be not rendered fit for the body to assimilate it, it might just as well not be given to the patient at all, in so far at least as the object held in view is concerned. As I know manufacturing pharmacians desire to aid the practitioner in combating disease and death by every means in their power, and that they are always willing to adopt all reasonable improvements both as regards the modes of preparation and the forms of administration of drugs, I trust the calling their attention to such an important therapeutical suggestion as the above—founded as it is on true physiological principles—in the pages of THE LANCET will have the desired effect.

I am, Sirs, yours faithfully,

Harley-street, W., May 22nd, 1896. GEORGE HARLEY.

[1] Plant Lore Legends and Lyrics.

"THE OPTICIAN *v.* THE OPHTHALMIC SURGEON."

To the Editors of THE LANCET.

SIRS,—My attention has been directed to the admirable article in THE LANCET of May 9th on the relations between oculist and optician, and I may say at once that I entirely concur with the spirit of your remarks; but in dealing with the matter—very naturally and rightly from the standpoint of the medical profession—you seem to me to do us traders rather scant justice, and I therefore crave permission for a few words from the point of view of the optician, and the essence of my protest lies in your use of the word "encroach." Surely, if the word is to be used at all it is rather applicable to the oculist than to the optician; but the word is not a nice one and I would prefer to represent the state of affairs in this way. The correction of defective sight by means of spectacles has remained for centuries almost entirely in the hands of the trader; but the great increase during the last thirty years in the knowledge of ocular refraction and the therapeutic use of spectacles has lifted the whole matter into the professional sphere. But in this connexion it should be recognised that we are still in a state of transition. I think the majority of opticians—those, at least, who have a due sense of the responsibilities involved—look forward hopefully to a time when people will go as naturally to the medical practitioner for advice on eye and sight troubles as they do now for defects of hearing. I think, too, they are doing good work, each one according to his opportunities, towards bringing that time about. But there are many difficulties that the optician has to meet, such as the refusal of people to take their defects of sight seriously, ignorant prejudice, the ingrained habit of old-fashioned customers, and, not least common, the specialist's fees. No doubt time will dissipate these difficulties, but meanwhile it would be generous—one might almost say just—to make allowances for them and to give the optician credit for doing his best to adapt himself and his business to the new conditions.

I am pleased to think that in my main view of our present duty I am absolutely in accord with the recommendations of your article. No encouragement should be given to proposals for measures, legislative or other, such as have recently agitated the State of New York. Feelings of rivalry should be restrained and the issue left to easy and natural development. I am, Sirs, yours truly,

New Bond-street, W., May 21st, 1896. W. A. DIXEY.

SHORTHAND IN MEDICINE.

To the Editors of THE LANCET.

SIRS,—With reference to the remark in your annotation on our petition to the General Medical Council I may point out that the petition is for "shorthand," and not any one system, to be allowed to bear some marks to those who choose to present it. The wide use of phonography has been, perhaps, unwisely referred to in the petition, but the College of Preceptors accept any system of shorthand as an optional subject at the same examination as is recognised by the Council. Those who are passing it for the medical profession, however, do not present shorthand because the General Medical Council has not included it as a subject for

Digitized by Google

which marks may be given. Any really legible system of shorthand will serve for personal use, but uniformity of system is necessary for intercommunication and for such help to acquisition and familiarity as our publications and circulating manuscript magazines present. Each of the latter is in effect a small society for the discussion of medical questions without need for proximity of the members. I have reason to think that many members of the profession and students have acquired shorthand who have not yet joined our society. May I take this opportunity of asking them to do so without delay and to write to Dr. Neil, Warneford Asylum, Oxford, our honorary secretary?

I am, Sirs, yours faithfully,

May 27th, 1896. W. R. GOWERS.

"POOR-LAW OFFICERS' SUPERANNUATION BILL."

To the Editors of THE LANCET.

SIRS,—The above Bill has been passed so rapidly through the committee stage that several very necessary amendments have not been inserted into it. Many months since it was pointed out to its promoters that the Bill as it stood would operate very strongly against the interests of trained nursing in Poor-law infirmaries, and, indeed, that the Bill appeared to be drafted in the interests of some of the superior officers, who would derive benefit from the salaries of their inferiors. Thus the trained nurse rarely stays any length of time in a Poor-law infirmary; the conditions under which her work has to be done are so antagonistic in most cases to the proper performance of those duties that she will not stay beyond her probationership or beyond the time she is bound by the terms of her training. Again, a trained nurse is past her work soon after fifty. At Guy's Hospital she is compulsorily retired at fifty, at the London Hospital at fifty-five. The Royal National Pension Fund for Nurses, it is true, puts the age for compulsory retirement at sixty, but at the request of the authorities of Guy's Hospital the nurses there are permitted to retire under their scheme at fifty, and they have recently added another table to their previous ones with a view to encouraging the retirement of trained nurses at this age. No one would voluntarily be attended by a trained nurse who was close on sixty years of age, yet the Bill I am referring to puts the voluntary age for retirement at sixty and the compulsory one at sixty-five. It is evident that under such regulations few trained nurses will enter Poor-law infirmaries. It is true that a recent amendment has been made to Clause 8, providing that any person not dismissed for her own fault shall have her payments returned to her, but there is a considerable probability that this clause may be interpreted to mean that the deductions from the salaries will only be returned if the nurse remain a certain minimum period of time, and this will operate as unfavourably as the original clause. I am informed that all the Poor-law infirmary authorities, nursing and medical, are strongly opposed to the Bill on these grounds, and I have no doubt but that if the required amendments be not inserted it will even now be blocked. It is so difficult to get the proper class of persons to take up workhouse infirmary nursing or even to enter as probationers that nothing which increases this difficulty will be tolerated. May I ask for your powerful support in this matter?

I am, Sirs, yours faithfully,

Fellows road, N.W., May 26th, 1896. F. R. HUMPHREYS.

"THE ARMY MEDICAL STAFF."

To the Editors of THE LANCET.

SIRS,—With your permission I would wish to endorse every word in the letter of "Brigade-Surgeon, A.M.S.," published in THE LANCET of May 9th. It is, I consider, the most to the point and the best of the many letters written on this subject. After more than a score of years spent in the service I have no hesitation in saying that the advances which have been made within my memory have been enormous. Never before was the soldier so well looked after in health and so well treated and nursed when sick, and never before would he be so well cared for in war, within the limits of numbers, as at the present day. I am confident that the soldier generally recognises this though his officer may not, as the latter no longer has his familiar friend—or drudge, as the case may be—"old pillbox" at his elbow. Let not the authorities hastily or unadvisedly sweep away this organisation, the result of care and forethought, and which has necessarily taken a generation of medical officers to bring up to its present, I maintain, high standard. Rather let them make the service, by one means or the other, sufficiently attractive to induce a desirable stamp of man to compete for it. The tangible grievances of the service are, I consider, three—viz., (1) the large proportion of foreign service, at present equalling about three-fourths of the whole; (2) the non-recognition of various warrants and ill-treatment of medical officers by the Indian Government; and (3) the frequent changes of station of junior medical officers at some of the home stations. The first two could be rectified by the Indian Government taking over the medical treatment of white troops in India, as I see has been frequently advocated of late; and considering the treatment they have received in India and the depreciated rupee I think the Army Medical Staff would be but little the losers. The abolition of half-pay appointments and a relatively larger number of medical officers serving at home, together with a headquarters order on the subject, would meet the third, which is an important one from the patient's point of view, as it often leads to change of medical men in treatment of his case. Most of the sentimental grievances would disappear in course of time with a generally higher class of medical officer, and at those which did not we could afford to smile.

I am, Sirs, yours truly,

May 23rd, 1896. ACTIVE LIST.

PROFESSIONAL CONFIDENCES.

To the Editors of THE LANCET.

SIRS,—Can you or any of your readers give me any help with regard to the following circumstances? A few days ago I was called in to see a young unmarried woman who had recently miscarried. On inquiring if any instrument had been used she admitted that it was so. For some days the patient was in a very critical condition, but is now going on all right. Ought I, seeing that the attempt to procure abortion is in itself a criminal offence, to report the case to the police?—I am, Sirs, yours faithfully,

May 26th, 1896. YOUNG PRACTITIONER.

*** We should say "No." The information was obtained *sub sigillo*, and we do not think it is the duty of a medical man to give information to the authorities under such circumstances as our correspondent details.—ED. L.

THE ST. GEORGE'S HOSPITAL GRAPHIC SOCIETY.—The annual general meeting of this society will be held at the hospital on Tuesday, June 2nd, at 2.30 P.M. By permission of the board of governors the annual exhibition, which is strictly limited to the work of members, will be held in the board-room of the hospital. The exhibition will be opened immediately after the meeting and will remain open until the end of the week.

THE DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual general meeting and conference of this society was held on May 20th, Dr. P. H. Pye-Smith, F.R.S., President, being in the chair. The reports of the council and treasurer were adopted and the following were elected office-bearers for the ensuing session:—President: J. F. Payne, M.D. Vice-presidents: Dr. McCall Anderson, Dr. J. Hughlings Jackson, Dr. Robert Liveing, Dr. P. H. Pye-Smith, and Dr. S. Wilks. Treasurer: Dr. Stowers. Council: Dr. P. S Abraham, Dr. R. Bowles, Dr. H. A. G. Brooke, Dr. J. Galloway, Dr. A. J. Harrison, Dr. S. Mackenzie, Dr. Walter Smith, Dr. F. Taylor, Mr. Anderson, Mr. A. Cooper, Mr. J. Hutchinson, and Mr. B. Shillitoe. Secretaries: Mr. L. A. Bidwell and Mr. G. Pernet. After a vote of thanks to the retiring President Dr. Payne took the chair and gave his introductory address on the Etiology of Diseases of the Skin, with special reference to impetigo contagiosa and eczema, and the *rôle* of micro-organisms. Dr. Walter G. Smith (Dublin) read a paper on the Properties of Chrysarobin and Chrysophanic Acid. Dr. Stopford Taylor, Dr. Waldo, and the President discussed the paper. The following cases were also shown:—Dr. D. Walsh: (1) Elephantiasis; and (2) Thimble Eczema. Dr. A. Eddowes: (1) Unilateral Lupus Erythematosus; (2) Ichthyosis; (3) Urticaria Papulosa; (4) Eczema of the Eyelid; and (5) Dysidrosis and Hyperidrosis. Dr. P. S. Abraham: Erythema Persistans, &c.

THE BATTLE OF THE CLUBS.—XXXI.[1]

(FROM OUR SPECIAL COMMISSIONER.)

(*Continued from p. 1380.*)

DERBY: THE ABORTIVE MOVEMENT OF 1872; THE APATHY OF THE PROFESSION; FEMALE CANVASSERS.

IT must at once be acknowledged that my investigations in the town of Derby did not lead to any encouraging conclusions. My first visit was to Mr. Francis, President of the Derby Medical Society, which was formed some four years ago. It is quite different to other medical societies. The society has about sixty members. They meet for social and convivial purposes and also to discuss scientific papers; but, according to Mr. Francis, the society is in no wise prepared or anxious to take up economical questions. At the same time I should also state that I met with younger members of the profession at Derby who held more hopeful views. They had less knowledge of past and disappointing experiences. It appears that in 1872 a requisition was signed by a large number of practitioners at Derby demanding increased pay from the various friendly societies and medical aid associations established at Derby. The case, I am told, was badly put and failed to excite public sympathy. A number of meetings were held in private houses and were supposed to be private meetings. Nevertheless, there were always one or two medical men present, who went and reported all that had occurred to the committees of the friendly societies. The feeling of solidarity among the members of the profession, it will be seen, was very weak, but as this occurred twenty-four years ago the fact should not dishearten the men of to-day. Ethics have made great progress within the last quarter of a century. The selfish sense of individualism is dying out; the new word and the new teaching of solidarity is gaining a firmer hold on the public conscience, and people in all trades and professions are beginning to realise at once the material necessity of unionism. In 1872, however, all friendly societies were well prepared and able to resist the demands of the Derby medical men. They amalgamated and formed a United Friendly Societies' Dispensary. They not only refused to continue the pay of their medical officers, but introduced three new practitioners, to whom they paid fixed salaries and to whom they entrusted all their patients. Thus the dissatisfied medical officers not only failed to obtain an increase of pay, but lost what little they had. Mr. Francis, however, succeeded in keeping his lodges of Oddfellows, who now pay him about £200 a year in a 3*s.* 6*d.* annual subscription for each member. Mr. Francis seemed quite satisfied with the arrangement. During the course of twenty years no complaints had been lodged against him; he had not once been summoned to appear in self-defence before the committee. He was, if necessary, able to attend to any private patient who might happen to call at his house during the hours set aside for seeing club patients. To use his own words, he felt the coming in, but did not feel the going out—that is to say, if the number of members increased he felt the financial benefit, but the extra work this might entail was less perceptible. As for having too much work to do he thought that serious cases among the club patients were generally well treated. Undoubtedly there were some abuses. Rich men made political capital of having belonged for twenty-five years to a friendly society and having never drawn a penny, but they were careful not to state how much medicine and medical advice they had obtained from the friendly society's medical officer. On the other hand, these wealthy and superior men were generally members of the committees of the friendly societies. Being more intelligent than ordinary workmen they had the good sense to hear both sides when a question or complaint was raised. These wealthy and superior members of the friendly societies were really a protection to the medical officers and saved the latter from much needless and vexatious worry. Seeing the utter failure of the movement attempted in 1872 Mr. Francis was not at all desirous to resume the struggle even under the present more favourable conditions.

My next visit to a neighbouring practitioner was not more encouraging. In answer to my questions the medical man in question informed me that he received £4 or £5 per quarter from the London and Manchester Insurance Company and that their members and patients gave him very little trouble. Though the profession in the neighbouring town of Nottingham have risen in arms against this very same insurance company the Derby medical officer of the company declared that he was not even aware there was an agitation against them.

My third visit was to a consulting physician, and he certainly did speak in contemptuous terms of the medical men who, in different parts of the country, were employed at fixed salaries at the dispensaries established by these friendly societies. He thought it was a mistake to imagine that the men who accepted such posts were all young and inexperienced medical men. But was he to render himself unpopular with all the workmen of the town by refusing to meet in consultation the medical officers of the friendly societies' dispensary? Why should he be called upon to "bell the cat"? He agreed that the poor members of friendly societies were the most neglected and received the worst attendance. It was clear that a medical man who had club practice, but aimed at ultimately obtaining a private practice, would give himself much more trouble with regard to these club patients who were better off and could afford to become private paying patients when he left the club. Thus the club medical officers lent themselves to the establishment of a system of favouritism which told to the disadvantage of the poorer members of friendly societies. Surely this evidence should be taken to heart by the working-classes. It should make them understand how completely it is to their own advantage that a wage limit should be established and that medical attendance should not be given to wealthy members of benefit or friendly societies. On their side the members of the medical profession should realise how thoroughly the friendly societies reduce their medical officers to the level of mere paid servants, and that the medical aid they organise is established, not as a professional matter, but as a pure matter of business. This is fully set forth in Rule 19 defining the duties of the managing committee of the Derby Amalgamated Friendly Societies' Dispensary. The rule is as follows and I italicise the important passages: "The managing committee shall purchase all necessary drugs, instruments, surgical appliances, furniture, fixtures, books, forms, and other items *for carrying on the business of the Association*, and make such arrangements for the efficient and proper working of the dispensary as they may deem necessary." ..... "*They shall draw up agreements* for the due fulfilment of the duties of the medical officers and dispenser, and submit the same to the general committee for their approval and see that such agreements are properly carried out. They shall also have *power to suspend* a medical officer or dispenser for any misconduct or breach of agreement until such time as the matter of complaint has been laid before the general committee (which must be as early as possible after a complaint arises), when, if complaint be proved, the general committee shall have power to request the committee of management *to dismiss with or without notice* such medical officer or dispenser *for any misconduct or breach of agreement*, and if notice to resign be given, such notice shall be for one, two, or three months, as may be determined by the committee."

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Aug. 24th, 1895, Brussels; (2) Aug. 31st, 1895, Brussels; (3) Sept. 21st, 1895, Portsmouth; (4) Sept. 28th, 1895, Portsmouth; (5) Oct. 5th, 1895, Eastbourne; (6) Oct. 12th, 1895, Lincoln; (7) Oct. 26th, 1895, Lincoln; (8) Nov. 2nd, 1895, Grimsby; (9) Nov. 9th, 1895, Bexhill-on-Sea; (10) Nov. 16th, 1895, Hull; (11) Nov. 23rd, 1895, Hull; (12) Dec. 7th, 1895, York; (13) Dec. 14th, 1895, Northampton; (14) Dec. 21st, 1895, Fermanagh Medico-Ethical Association; (15) Dec. 28th, 1895, Northampton; (16) Jan. 4th, 1896, Birmingham; (17) Jan. 18th, 1896, Birmingham; (18) Jan. 25th, 1896, Club Practices in Rural and Mining Districts; (19) Feb. 1st, 1896, The Formation of a Provident Medical Association at Folkestone; (20) Feb. 8th, 1896, The Manchester Medical Guild and Medical Aid Associations; (21) Feb. 15th, 1896, The Leicester and Leicestershire Provident Dispensary; (22) Feb. 22nd, 1896, The Organisation of the Profession at Leicester; (23) March 7th, 1896, Loughborough: Local Efforts Defeated by Consultants from Neighbouring Towns; (24) March 14th, 1896, Medical Aid Societies in Small Heath; Medical Clubs at Stockport; (25) March 21st, 1896, General Meeting of the Profession and the Formation of a Union at Nottingham; (26) April 4th, 1896, Nottingham; the London and Manchester Industrial Assurance Company, Limited; the Public-house Medical Aid Clubs; United Action at Lincoln; (27) April 11th, 1896, Leicester and Wolverhampton; a Hastings Dispensary wound up; (28) April 25th, 1896, Walsall, Formation of a Medical Union; the Medical Profession and the Friendly Societies; Trade and Medicine; the Family Clubs; Women's Public-house Clubs; (29) May 9th, 1896, Sheffield: An Ancient Medical Society; Workmen Sweaters; The Old Grievances; Probable Formation of a Medical Union; (30) May 16th, 1896, Lincoln: Medical Protection Fund Started; Benefit Societies and Medical Men; Medical Union at Nottingham.

Digitized by Google

Such dispensaries are not only injurious in themselves to the interests of the medical profession; they compel medical men who try to start private dispensaries of their own to accept equally low terms. But such private dispensaries are slipping out of the hands of the profession, they are better organised, or rather more actively pushed by the canvassers in the employ of insurance companies. As agents canvass so actively for these companies, medical men who have private dispensaries of their own now also employ a canvasser, so that, as far as the dignity of the profession is concerned, it all amounts to much the same thing. I was assured that at Derby there are some private dispensaries where even girls are employed to collect and to canvass for subscriptions. So keen is the competition that members of medical aid associations or dispensaries are emboldened to make exorbitant demands on their medical officers. One club medical officer complained that he was compelled to give death certificates for nothing, though the Registrar who only copies the medical certificate is always paid for such copies.

There is also at Derby a sort of charitable provident dispensary, and at this institution, after the drug bill, the dispenser, and other expenses have been paid, there only remain 2*s.* per annum per member for the medical officers. It will be seen, therefore, that club practice at Derby stands at a very low ebb; but what is far more discouraging is the fact that at present no action is being taken to remedy these evils. Perhaps, however, when the Derby practitioners read what has been attempted and already achieved in many other towns they will awake from their present lethargy. In any case the younger members of the profession with whom I discussed the matter agreed that nothing but a strong union could save them from still further degradation. Unfortunately these younger men are not sufficiently influential to start the movement, and in the higher ranks of the profession there unfortunately at present prevails much apathy.

THE GAINSBOROUGH DISPENSARY.

It seems to be a generally recognised rule among the members of a certain class that workers of all kinds are entitled to full payment for what they do, except in the case of medical men. At the annual meeting of the Gainsborough Dispensary a "requisition" was read from the medical officers of the dispensary, and the following are the main points of the said requisition. In 1872 the remuneration of the medical officers was fixed at 66⅔ per cent. of the whole sum received by the dispensary. From 1884 to 1894 the sums received by the medical officers have varied between 50 and 57½ per cent., thus falling far below the remuneration fixed by the rules of the institution. Other sections of the requisition dealt with the boundaries of the district, the payments of members, fines, &c. It appears that the medical men attached to the dispensary who drew up the requisition held sundry meetings to consider it. They were all unanimous in its favour, and all signed it. Then arose the question what should be the course of action in the event of the Dispensary Committee refusing to accept the requisition, and according to our information they came to the conclusion that if the committee rejected it they would withdraw it. This seems to be a weak method of procedure. It savours too much of "These are my opinions, gentlemen, but if you don't like them I shall be happy to change them." The example of Cork shows what can be done by steady refusal to work for inadequate sums and by firm organisation. The tone of the Dispensary Committee was not of the best, witness the speech of one member, who, according to the *Retford and Gainsboro' News*, characterised the requisition as an "audacious solicitation" and also talked about "two new doctors." Despite the efforts of the chairman to secure a just and equitable settlement the requisition was withdrawn. Now, we have no knowledge of the circumstances other than we have procured from newspapers, &c., but if the medical men of Gainsborough want their bond they will have to fight for it. It is no possible use saying, "We want this, but if you say 'No' we won't ask again." A little firmness, a little unanimity, and the battle will be won.

LINCOLN MEDICAL PROTECTION FUND.

To the Editors of THE LANCET.

SIRS,—The following subscriptions have been received to the above fund since you so kindly published our appeal of the 16th inst.:—

	£	*s.*	*d.*
J. B. Neale, New Wandsworth	1	1	0
H. T. Butlin, Harley-street, W.	5	5	0
T. T. Blease, Altrincham	2	2	0
E. E. Llewellyn, Ramsey, Hunts	1	1	0
Portsmouth Medical Union	2	2	0
H. C. P. Howes, Lincoln	2	2	0
C. Arblaster, Madeley, Salop	0	10	6
H. P. and G. C. Taylor, Trowbridge, Wilts	3	3	0
F. Cassidi, Derby	1	1	0
H. Meadows, Leicester	1	0	0
C. H. Marriott, Leicester	2	2	0
R. H. Dawson, Saundby, Notts	1	1	0
Previous list	119	10	0

Two of the late officers of the medical clubs are now associated with the New Lincoln Provident Medical Association, whilst the third is at present engaged in *locum tenens* work. It is impossible as yet to estimate the amount that will be required for the purposes of the fund, but should the practical sympathy of the profession enable us to carry on for a few months we have every hope of an ultimate victory. Mr. C. Brook, Dr. C. Harrison, and Mr. G. Mitchinson, together with myself, have been appointed trustees for the fund.

I am, Sirs, yours truly,

Lincoln, May 28th, 1896. W. A. CARLINE, Hon. Treasurer.

"A DOCTORS' STRIKE."

To the Editors of THE LANCET.

SIRS,—May I, as a general practitioner, thank you and your Special Commissioner for the able and interesting way in which you are calling the attention of the medical profession to their present state of degradation? It appears that now is the time for us, as a body, to work out our salvation in this matter. The defeat of the profession at Lincoln and other places would clearly mean the subserviency of the profession to the medical aid associations and the absence of wage limit and the continuation of the present small rate of pay. I append a cutting from our local paper showing that in places medical men whose demands are reasonable suffer temporarily from our want of union. THE LANCET, since the days of its founder, has been the friend and journal of the general practitioner. I would suggest that you should:—

(*a*) Issue a circular to all medical men and students stating the principles contested—viz., (1) the establishment of a wage limit; (2) the abolition of paid canvassers and medical aid associations as at present constituted; and (3) the increase of rates of club pay—and asking them to subscribe to the same and join an association for the establishment of the same.

(*b*) Open a subscription list to help to carry out these objects. If every medical man in practice subscribed from one to three guineas, according to his means, you would have a fund of at least £20,000 to compensate those who may lose appointments and to enable those with little means to tide over their temporary embarrassment.

(*c*) Form a central and local committee to carry out the above objects. If your journal would undertake this it would earn the gratitude of all general practitioners and especially that class whose livelihood depends on club-work.

Yours faithfully,

May 23rd, 1896. CLUB DOCTOR.

[Cutting.]

A Doctors' Strike.

The medical men of —— and —— (near ——) recently gave notice to the friendly societies of the district that after next month they would not attend patients for 4*s.* a year as before, and also that they would not accept men earning 30*s.* a week as club patients. These demands are not assented to by the members, who are a numerous body, and the difficulty has been overcome by the appearance of a new resident medical practitioner, who has taken over the clubs on the old terms.

*** Our correspondent states very clearly the principles which are at issue in the present crisis of the profession in regard to club practice—(1) the establishment of a wage limit; (2) the abolition of canvassing and touting in all forms; and (3) the increase of rates of club pay. THE LANCET has sufficiently often published these points, so as to leave any member of the profession who disregards them or who takes the place of a medical officer who suffers for asserting them without excuse. It remains for the profession in each locality to apply principles so just and to organise club arrangements on the spot in which these principles shall be recognised. There remains the question

Digitized by Google

f the treatment of the "appearance of a new resident ıedical practitioner to take over the clubs on the old terms." 'he provision of a fund for indemnifying sufferers is worth onsideration; but more is to be done by firm action and rganisation.—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Ladies' Charity and Lying-in Hospital.

THE medical staff of this charity have remained unaltered ı their attitude. The epithets of "brutal" and "inhuman," 'hich have been so freely bandied about, are now, I am glad ɔ say, found to have been most unfairly bestowed on conuct that was the only possible course of action consistent ·ith dignity.

Intramural Interments.

The report of the medical officer of health on intramural ıterments, issued at the request of the health committee f the City Council, contains some interesting reading. 'r. Hope says that interments under certain conditions are ;ill permitted in eleven burial-grounds in Liverpool; upon ıe use of some of these the Home Office places certain ·strictions. The numbers of applications to the medical fficer of health for permission to inter in city graveyards, here such application is necessary, have during the last five ears been respectively 64, 69, 42, 58, and 56. The largest umber of interments appears to take place at the Necropolis, here notice is not required to be sent to the sanitary departıent, though occasional visits are made to it. At this burialround there is an arrangement of tiers, separated by a course f flagging and with brickwork between each coffin. The alls between the vaults are 4½ in. in thickness, and a stone ag covers over the top course of coffins about 2 ft. 6 in. elow the surface of the ground. The vaults contain about ıirty-six coffins. The approximate number of interments ıot including "stillborns") which have taken place at this ·metery since it was opened is 82,341. The occupiers houses abutting on this cemetery state that their houses ·e infested with mice of a peculiar light-fawn colour, hich they believe come from it. Among other in·resting matters Dr. Hope mentions that instances have ·me under his notice where municipal necessities have d to the absorption of parts of a city graveyard in which .e remains of more human beings have been found beneath single tombstone than the record on the tombstone indi·ted. He concludes his report by saying that "whilst the scontinuance of the practice of interment in burial-grounds tuated in populous parts of the city cannot be otherwise an advantageous to the general public it need not be tended with any hardship to those immediately interested."

Hospital Saturday.

The annual street collection to supplement the weekly ntributions made during the year in workshops, warehouses, and offices on behalf of the local hospitals took ace on the 16th inst. Three hundred and fifty ladies, cluding many hospital nurses, devoted the whole day to e collection. No place where there was a chance of ·tching a copper was neglected by the fair and persistent endicants. Particular attention was paid to the railway ·ations, the landing stage, and the flags of the Exchange. y means of their efforts over £500 were obtained. When is amount is added to the Fund resulting from the weekly llections made all the year round in the above-mentioned ·siness places a goodly sum will be available for distribution the local charities.

The City Hospitals and Police Ambulance.

A deputation from the representatives of the working men the committee of the Hospital Saturday Fund recently ·ited on the Watch Committee of the City Council to urge e necessity of establishing a police horse ambulance corps an auxiliary to the hospitals. The proposal was favour·ly entertained by the committee, who have instructed the ad constable to report on the subject.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Resignation of the President of the University College of South Wales and Monmouthshire.

AT a special meeting of the Court of Governors of the University College of South Wales and Monmouthshire held on May 13th a letter was read from the Dean of Llandaff resigning his position as president of the College on the ground that his medical adviser debarred him from the exertion which his appearance in public at the installation of the Prince of Wales as the first Chancellor of the Welsh University would involve and a motion which had been moved by the chairman asking Dean Vaughan to reconsider his decision was seconded, but upon a statement being made by the Dean's medical attendant in reference to his health and stating that the very greatest kindness that could be done was to accept the resignation, the chairman thought it would be cruel to proceed any further with his motion and he accordingly withdrew it. The Dean of Llandaff's resignation was, therefore, regretfully accepted.

Freedom of Bristol from Small-pox.

At the meeting of the Bristol sanitary authority held on May 21st the medical officer of health (Dr. D. S. Davies) reported that no case of small-pox had been notified since May 9th. There are only seven cases in hospital and all convalescent. No cases have been left at home. From inter-notification returns the outside districts also appear to be remarkably free. The only case to cause any anxiety is one in St. George, Gloucestershire, left at home, for though no doubt every care is being exercised, home-nursed cases are always a source of considerable danger, as shown in Gloucester, when the outpacing of the hospital accommodation promptly sent up the weekly returns from 70 or 80 to a maximum of over 200 per week.

The Annual Meeting of the Bristol Branch of the National Society for the Prevention of Cruelty to Children.

The annual meeting of this Society was held on May 20th, under the presidency of the Mayor. The report stated that during the past year the complaints of cruelty brought before this branch of the society numbered 304, and of these 286 were, upon investigation, found to be true. These involved 339 offenders, and affected the welfare of 468 children. The cruelties complained of included—exposure for begging purposes, &c., 22; ill-treatment and assault, 57; neglect and starvation, 207. Of the children affected 33 were found to be insured for sums which in the aggregate amounted to £180. The 286 well-founded complaints were dealt with as follows—warned 225; prosecuted (of whom 58 were convicted and 3 discharged), 61. The majority of offenders were parents. The contributions received during the last year amounted to £567, being an advance of about £100 upon the sum raised in the corresponding period of 1894–95, and the accounts show a local surplus of £125.

Aberystwith College.

Having furnished the Government with the necessary certificate that the college authorities had raised the stipulated sum of £5000, the Registrar of the University College of Wales, Aberystwith, has just received a cheque for £5000, being the last instalment of the conditional grant of £10,000 promised by the Government.

Suggested Visit of the British Association to Bristol.

On May 18th an important deputation, representing the University College, Bristol, the Bristol Medical and Chirurgical Society, and the other scientific societies and institutions of Bristol waited upon the Mayor of that city and asked him to invite, in the name of the citizens, the British Association to visit Bristol in 1898. Professor Lloyd Morgan mentioned that the British Association had been in existence sixty-five years and had met in Bristol twice, in 1836 and 1875, and the feeling of the societies represented that day was that the time had come when Bristol should put in a claim to invite the Association to visit them a third time. The Mayor stated that he would be very pleased to further the invitation.

The South Wales University College.

A meeting was held at Bridgend on May 21st, under the presidency of the Earl of Dunraven, in support of the special building fund of £20,000 for the South Wales University

Digitized by Google

College. His lordship promised a donation of £400, and altogether a total of £680 was promised.

The Prevention of Floods in Bristol.

The Bristol Town Council has adopted the report of the Floods Committee, which recommended relief culverts for the prevention of flooding from the Cutler's Mills and Boiling Wells streams, the further improvement of the river Froom, and the erection of pumping machinery for accelerating the discharge of flood water from the harbour, the estimated cost for the various works being £90,000. It is stated that this scheme will deal with any rainfall similar to any that has ever occurred in Bristol, and consequently there ought not to be a recurrence of such floods as were recorded in THE LANCET of Nov. 20th, 1895.

Accident to a Medical Man.

On May 16th as Dr. Moynihan and his wife, of Northover, Ilchester, were driving home from Yeovil, the horse bolted, and both the occupants of the trap were thrown out. Dr. Moynihan fell with great violence upon his head. He was at once taken to the Yeovil Hospital, where it was found that he was suffering from a fractured skull, and it is feared that he will not recover. His wife sustained only a slight injury. Dr. and Mrs. Moynihan have only been married about a fortnight.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Dr. George Hare Philipson.

FOR twenty-eight years Dr. George Hare Philipson has occupied the post of physician to the Royal Infirmary in this city. The time has now arrived when by statute his services can no longer be retained as a visiting physician. Dr. Philipson has taken leave of his class and intimated to the weekly committee that the statute applies to him, so that there can be little doubt that a vacancy will be soon declared. It will be no easy task for anyone to succeed Dr. Philipson. There will be no difficulty in finding another physician, but for many years to come the gap made by his absence from the wards will be apparent to all acquainted with the working of the infirmary. Punctual, courteous, and kind, his example will be one worthy of imitation, difficult to equal, and impossible to improve upon.

Opening of a new Out-patient Department in connexion with the Hospital for Sick Children in Newcastle-on-Tyne.

The Hospital for Sick Children is situated on the Moor Edge, a considerable distance from the centre of the town. It is a very beautiful little hospital and was given to the town by the late Mr. Flemming, a wealthy solicitor. The out-patient department opened this week is in the centre of the town. It is the gift of Lord Armstrong as a memorial of the late Lady Armstrong. It was opened with a golden key by Mr. W. Cruddas, M.P., and the deeds were handed over to the Right Worshipful the Mayor on behalf of the trustees and governors of the charity. There is no more popular institution in Newcastle than the Hospital for Sick Children, and the work done there is great in amount and good in quality.

Annual Meeting of the Eye Infirmary, Newcastle.

The usual decorum, not to say dulness, of the annual meeting of this charity was somewhat departed from last week. The vicar of Newcastle occupied the chair, and there was a larger attendance of subscribers than is usual. Dr. Jeaffreson read the annual report, after which an attempt was made to alter the rules. At present the staff consists of two surgeons, one of whom has just resigned, so that there is a vacancy. It was sought to increase the number of surgeons from two to three and to allow any registered medical practitioner to be eligible for office. Under the existing rules it is necessary that a surgeon to the Eye Infirmary should be a Member or Fellow of one of the Royal Colleges of Surgeons. After a lively discussion it was determined that there should still be two surgeons and that Masters in Surgery should be eligible as well as Members and Fellows of the Colleges of Surgeons. There were five applicants for the post of surgeon, two of whom were ruled to be ineligible. From the other three—viz., Charles Lightfoot, M.D., M.C. Edin., M.R.C.S. Eng., T. G. Ouston, F.R.C.S. Eng., and A. S. Percival, M.A., M.B., B.C. Cantab., M.R.C.S. Eng.—a selection will be made by the special committee shortly. Much interest is taken in the appointment, which is certainly a very important one for this district.

The Heatherdene Convalescent Home, Harrogate.

This useful institution, in connexion with the Sunderland Infirmary, was opened in September, 1892, for women and children. In 1894 the foundation stone of a new wing for men was laid by Mrs. Laing of Sunderland. This wing has cost upwards of £4000, and last Wednesday it was declared open by Mr. Laing and to be free from debt. The building will now accommodate forty patients.

Thirty Years' Service as a Poor-law Medical Officer.

Mr. B. Maclaren has tendered his resignation of the post of Poor-law medical officer for Bedlington. On the motion of the Rev. and Hon. M. C. Ellis it was agreed to put on record an expression of the high opinion held by the board of Mr. Maclaren's thirty years' work and of regret at losing his services. The chairman said Mr. Maclaren had been a good officer against whom they had not had a single complaint.

A Pamphlet.

A pamphlet headed "Juvenile Depravity, a Tale of the Newcastle Workhouse in 1895," is being pretty extensively circulated here just now. It alludes to discreditable circumstances which lately occurred in the workhouse in connexion with which a man formerly the boys' warden died suddenly while awaiting his trial. The pamphlet strongly suggests that a grave injustice has been done to an innocent man. However this may be, no one can read it without feeling very strongly indeed that the master of a large workhouse should be a properly paid educated man of better social standing than that from which masters are generally selected. The charge of a large workhouse with its sick, imbecile, aged, and juvenile inmates is an important one, quite as much as—most people would say more than—that of a governor of a gaol. It should certainly be occupied by men of as good position as those who are responsible for the custody of felons. Nine-tenths of the friction which arises from time to time in workhouse administration between the medical officer and the master would undoubtedly cease to arise if the master were a man of better social standing.

Newcastle-on-Tyne, May 25th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Opening of the University Athletic Field.

ON Saturday of last week the new athletic field for the University of Edinburgh was formally opened by the Lord High Commissioner. Much interest was evinced in a cricket match between the University eleven and the staff of the Royal Infirmary. The former played with broomsticks. The Infirmary team included Mr. Chiene, Dr. Bramwell, Mr. Cotterill, Mr. Cathcart, and others, most of whom had not touched a bat for years. The University eleven won, and several of the Infirmary eleven experienced the following day the discomforts consequent upon unusual exertion. The ceremony and the match were, however, regarded as having been most successful.

The Lord High Commissioner.

As is usual when Her Majesty's representative is at Holyrood the Royal colleges and other important bodies have during the present week paid their respects to him. He and Lady Tweeddale have on their side visited the Infirmary and other institutions, at all of which they were gladly received, their visit always being a source of interest and pleasure to the patients.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Unfounded Charge against a Medical Man.

ON the 26th inst. in the Northern Dublin Police-court Mr. Frederick P. Smith of Kevit Castle, Crossdoney, county Cavan, was charged before Mr. Keys, Q.C., with having feloniously assaulted a servant girl at Wellington-place, Clyde-road, between nine and ten o'clock on last Thursday night. According to the girl's statement she left the festivity

Digitized by Google

at Ball's Bridge at about nine o'clock and went towards her master's house. In Wellington-place she was attacked by two men, one of whom held her down while the other ravished her. On Monday—that is, four days after the occurrence—she went to Cyclopia with a policeman and identified the accused. Mr. Drummond, Q.C., stated that the accused was a medical man, having been qualified for about a year, that having by the death of a relative come in for some property in the county Cavan he had ceased to practise his profession, and, finally, that he (the learned counsel) would prove beyond the shadow of a doubt that the case was one of mistaken identity. Mrs. Saunderson (the wife of Colonel Saunderson, M.P.), in answer to Mr. Drummond, deposed that she was in charge of the Cavan stall at Cyclopia, Mr. Smith being one of her assistants, and that he was present at the bazaar between nine and ten o'clock on Thursday night. The witness, moreover, asserted, in reference to the girl's statement that the person whom she accused was dressed in light tweed, that Mr. Smith wore a suit of black. Mr. Edward Saunderson (the son of the last witness) deposed that Mr. Smith was in the stall with him during practically all the evening until it closed. Mr. R. W. Reeves stated that he was a deputy-lieutenant for the county Clare and that he was assisting at the county Clare stall, which was situated close to the Cavan stall, and that he saw Mr. Smith preparing to close up the Cavan stall at half-past nine on Thursday night. The defendant, Mr. Smith, was then called, and stated that on Thursday he was at the bazaar from two until after eleven o'clock. Some other witnesses were also examined, after which Mr. Drummond said that it was plain as daylight that the case was one of mistaken identity. Mr. Keys at once concurred, stating that he looked upon it as a case of mistaken identity and that he would dismiss it. Mr. Smith after leaving the dock was warmly congratulated by a large crowd of sympathising friends.

The Inquiry at the North Dublin Union.

At the last meeting of the board a resolution was adopted asking the Local Government Board to hold a sworn inquiry in reference to the allegations contained in a letter from Mr. Kennedy as to the management and discipline of the house.

Downpatrick Water-Supply.

A public meeting of the Downpatrick ratepayers was held on May 18th at which a resolution was adopted protesting against the unsatisfactory and deplorable state of the Downpatrick water-supply and works and the delay on the part of the board of guardians in dealing with the matter. It was stated that a tax of over £500 annually is being paid for which the inhabitants received practically no equivalent. A strong resolution was passed condemning the board of guardians for their indifference and incompetence in the exercise of their sanitary powers, and pressing the Local Government Board, in the interest of the ratepayers and to prevent indefinite waste of time and money, to take the conduct of the matter entirely out of the hands of the board of guardians or compel them to proceed without delay to remedy the defects in the works. An influential committee was appointed to look after the interests of the ratepayers in the matter of the water-supply.

The Ulster Eye, Ear, and Throat Hospital.

The foundation-stone of the new wing to be added to this hospital was laid on May 20th by Miss Benn and the Lady Mayoress of Belfast. This new part of the building will contain five small wards, two bath-rooms and closets, and a spacious operating-room. The present hospital was opened in 1871, a quarter of a century ago. In the next year Mr. Edward Benn (brother of one of the ladies who laid the foundation-stone) offered to build a new hospital, which he did at a cost of over £3000, and it was opened in 1874. His brother, Mr. George Benn, gave during his lifetime £1000 to endow the hospital and also in his will bequeathed a similar sum for the same purpose. In the working of the hospital it was soon seen that additional accommodation was needed for day-rooms, operating-theatre, bath-rooms &c., wards, and laundry. The laundry, bath-rooms &c., and two day-rooms in, or connected with, the old building are completed and it is expected the rest of the extension will soon be ready. When finished the new Ulster Eye, Ear, and Throat Hospital will be complete in every respect.

Opening of County Monaghan Infirmary.

On Friday, May 22nd, his Excellency Earl Cadogan, Lord-Lieutenant of Ireland, who has been paying a visit to Lord Rossmore, performed the opening ceremony of the new county infirmary in the town of Monaghan, a place which was once represented by an ancestor of Earl Cadogan. The old infirmary, built in 1768, was for a long time found to be in every respect unsuitable, and when the grand jury put up the old county prison for sale the board of governors of the infirmary bought it for £550. The southern portion of this building has been altered and transformed into a hospital at a cost of about £2000, the money for this purpose being raised by a bazaar. There are seventy beds in this new infirmary. One of the wards was named after the present surgeon to the hospital—Dr. J. Campbell Hall—by the governors in appreciation of his services to bring the new arrangements to a successful issue. Mrs. and Miss Murray-Ker have given £250 to furnish two wards, another gentleman has furnished another, while a fifth ward has been named the "Young Ward," in memory of Mr. A. K. Young, who was for fifty-three years surgeon to the institution and who was one of the best-known medical men in Ulster. The Lord-Lieutenant was most enthusiastically received at the infirmary and was presented with an address. He declared the new hospital opened.

The Proposed New County Derry Asylum.

While in Belfast the coroner and others are doing all they can to prevent lunatics from being sent from the asylum to the workhouse in County Derry, the greatest opposition is being shown to the proposed enlargement of the asylum. It is admited that more accommodation is needed, but the great majority of the ratepayers think plenty of room can be found in the empty workhouses, and thus a large expenditure can be avoided. On May 23rd a most influential meeting was held in Coleraine, and resolutions were carried to the effect that the present was a most inopportune time to further burden the ratepayers of the county by throwing upon them the increased taxation arising from the building of a new asylum. This, it was said, would cost £120,000, and, owing to the present depressed state of agriculture, it was argued that it would be wiser to postpone the whole matter for the present. It is admitted on all hands that the present asylum is overcrowded, but it is thought the proposed legislation dealing with the amalgamation of unions (which must soon come) will solve the difficulty. Coleraine Union can accommodate 1000 inmates, while at present it has only 120; Limavady Workhouse was built for 800 or 900 inmates, while, as a rule, there are only 100 paupers in residence. Hence there is accommodation vastly in excess of what is needed, and if they were amalgamated one of these large workhouses would be empty and it could be utilised as an auxiliary asylum, and so the taxpayers would be saved the enormous expense of £120,000. Great dissatisfaction is also felt in the constitution of the board of governors of the County Derry Asylum, as out of twenty-three governors only three, it is said, really represent the county, the remainder having their interests centred in the city of Derry. The resolutions passed at the meeting are to be sent to the Lord-Lieutenant, the Chief Secretary, and the Board of Control of Asylums. Opposition to the enlargement of the asylum is being organised all over County Derry.

Museum for Londonderry.

An effort is at present being made to establish a museum in the historic city of Derry, and it is suggested that Gynn's Institution might be let for the purpose of a museum at a nominal rent. There is a nucleus of a museum, which was some time ago handed over to Mr. Bernard, and at present the articles are being arranged in suitable cases. They are chiefly minerals. Moreover several local gentlemen have private collections which would probably be forthcoming if a suitable habitation was obtained. Mr. Bernard, whose stock of relics and curios is a most valuable one, has expressed his willingness to hand them over to a local museum, and Sir J. A. MacCullagh, M.D. Dub., has also a series of relics specially associated with the past history of Derry. It is hoped a building will soon be set apart for the museum.

Belfast Royal Hospital.

At the quarterly meeting held on May 25th it was reported that 462 intern and 5733 extern patients had been treated during the past quarter. To the end of the quarter the expenditure has been £5940 14*s.* 5*d.*, and the receipts £5441 4*s.* 6*d.*; the expenditure has, therefore, exceeded the income by £499 9*s.* 11*d.*, but as a bequest of £500 is not available (without the sanction of the corporation) the expenditure exceeds the ordinary income by £999 9*s.* 11*d.*, which,

Digitized by Google

adding the debt of last year (£142 4s. 10d.), shows a balance against the hospital of £1141 14s. 9d.

May 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Cocaine v. Guaiacol.

A FEW months ago MM. Lucas-Championnière and André vaunted the superiority of guaiacol over cocaine as a local anæsthetic, claiming that, employed in the form of subcutaneous injections, it conferred greater analgesia than the better-known cocaine. M. Reclus[1] now takes up the cudgels for his favourite anæsthetic after a fair comparative trial of the rival drugs. Eliminating those cases where (owing, perhaps, to defective technique) sphacelus ensued, and another where (owing, perhaps, to idiosyncrasy on the part of the subject) analgesia was nearly *nil*, he tells us that he has employed guaiacol in the following operations. Circumcision: six centigrammes injected; incision seven minutes later with violent pain. Cocaine (three centigrammes) then injected; pain *nil*. Resection of saphenous vein: half of the field of operation anæsthetised with guaiacol and half with cocaine; freedom from pain only in the cocainised area. The same results occurred in a case of radical cure of hydrocele and in one of castration. As for the dangers of cocaine, M. Reclus once more states that observance of the following fundamental rules suffices to avoid them. Use only a 1 per cent. solution and never inject more than twenty centigrammes, a less quantity almost always being ample. The patient must be lying down, and the piston of the syringe must be pushed progressively as the needle enters in order to avoid the introduction of a large quantity of the drug into a vein that may be pierced. The patient remains on his back for an hour or two after the operation and must eat something before he rises. With these precautions M. Reclus has thus practised 3500 operations without the slighest accident either during or after the operation. With a hypodermic dose of ten centigrammes he has done the radical cure of hernia, and with fifteen centigrammes a castration. He concludes that cocaine should be preferred whenever the incision is not too long, and that its superiority over guaiacol is an established fact.

Chronic Glaucoma: its Varieties and their Treatment.

M. Abadie[2] states that there are two varieties of chronic glaucoma. In one the symptoms are intermittent. The patient says he sees occasionally iridised circles around flames, vision is dulled and confused for a few hours, and then becomes normal. This form may be advantageously treated by iridectomy, which is, however, useless in the second form, where the progression of the morbid process and symptoms is uniformly slow, silent, and continued, revealing itself only by an increasing loss of sight corresponding with the proportional elevation of the intraocular tension. In this kind of glaucoma, which is perhaps the more common and which affects both eyes consecutively, neither iridectomy nor repeated sclerotomy is of the slightest use, the only benefit accruing being at best a temporary lowering of the tension and a consequent remission. But M. Abadie informs us that there exists a form of treatment which is efficacious in this hitherto incurable disease. Commence first with the administration of potassium bromide and sulphate of quinine in daily doses of one or two grammes and half a gramme respectively. Locally instil each day two drops of a ½ per cent. solution of eserine. As soon as the tension has become normal leave off gradually the bromide and the quinine, but continue indefinitely the instillations, the solution of eserine being carefully sterilised so as not to irritate the conjunctiva.

A Practical Gift.

Dr. Brouardel, the Dean of the Paris Faculty, has received from M. Lépine, the Prefect of Police, and some of his friends a subvention of 2000 francs to pay the expenses of the initiation of students who have completed their curriculum and junior practitioners into the diagnosis and therapeutics of diphtheria (bacteriology, sero-therapy, and intubation). Such a gratuitous post-graduate course will doubtless prove most useful to students who have not enjoyed the advantages of the *internat*.

[1] Académie de Médecine, May 19th, 1896.
[2] Société Française d'Ophtalmologie, Congress, May 7th.

Commercial Currant Jelly.

At a recent meeting of the Société Française d'Hygiène M. Tison revealed the real composition of a product consumed by the ingenuous Parisian as currant jelly. It is simply agar-agar coloured and flavoured with certain essences which confer on it the appearance and the taste of fruit. Strange as it may appear, the authorities refuse to prosecute the sellers of this article, provided it be labeled *gelée groseillée*, their contention being that its consumption is not injurious to health. I suppose this is one of the advantages civilisation and nineteenth century chemical progress bring in their train.

May 26th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

For the Prisoners of War and the Maimed.

IT is necessary to go back to the French disaster at Moscow in 1813 for something like a parallel to the miseries and humiliations brought upon Italy by her invasion of Abyssinia. Discomfiture on the battle-field she has had to endure; but the suffering and the torture it has entailed have tested her moral courage still more. Her wounded soldiery now under treatment in her hospitals are perhaps the best off among her victims of the war. Would that she could persuade herself that her sons, now captives in Abyssinian keepin , were equally well cared for. These are estimated to amount to some 5000; many of them are wounded, all of the m feel the privations of a prisoner's life under semi-barbarous conditions, and, to add to their misery, there is the torturing conviction that their families in the mother-land are still in agonies of suspense as to whether they are dead or alive, well or ill, whole or mutilated. But Italy has proved equal to the demand on her head and heart in this crucial moment; and certainly her energy and self-sacrifice go far to reassure her foreign friends as to her future rehabilitation and prosperity. Beginning with the King the subscribers to the fund in aid of the prisoners embrace all classes and all creeds, religious and political. The committee, whose president is the ex-War Minister, General Mezzacapo, has up to this collected 700,000 lire (£28,000). Count Rinaldo Taverna, representing the Red Cross and its workers in the same cause, has just added 300,000 lire (£12,000) to the 1.000,000 lire (£40,000) previously contributed. The leading journals throughout the kingdom are so many centres for subscriptions which come from the poorest villages as well as the richest towns; while the colonies, chief among which is the Argentine Republic, have already sent in over 300,000 lire. Great Britain has a considerable Italian population, which has also responded nobly; and the ladies of Italy, headed by one of the *grandes dames* of the Court (the Countess Sforza di Santafiora), have conceived the project of sending to South Abyssinia an eminent ecclesiastic, charged with comforts of every kind for the captives. A similar initiative has been taken by Count Costantino Wersowitz-Bey, a Bohemian by birth, but a warm sympathiser with Italy. With a few companions he starts immediately for Obock, whence in thirty-eight days he will reach Antoto. There he expects to find King Menelik, to whom he carries the most authoritative credentials and whose good offices in behalf of the prisoners he is more than likely to conciliate. Among his *impedimenta* are many bales of linen, chests containing clothes, medicines, and creature-comforts of all kinds. More acceptable than any of these, he bears a huge trunk filled with letters from dear ones at home, letters which if they reach those to whom they are addressed will prove the best of restoratives to many a yearning heart. The Count, I may add, is reinforced by the Vatican, and embarks on his mission with the Apostolic benediction and the substantial aid of the dignitaries of the Roman Catholic Church from the supreme Pontiff downwards. Nor is it only for the relief of her own sons that Italy is now straining her resources, moral and material. The poor Ascars, those native troops who fought so well for her at Abba Carima, claim her warmest solicitude—many of them maimed in the most horrible manner by the more savage of King Menelik's soldiery. She has in this department of her relief operations the countenance of the "Arms and Legs Charity," whose headquarters are in this city—a charity started about seventeen years ago by the late General H. H. Maxwell, C.B.,

Digitized by Google

to whose nobly philanthropic life a touching tribute was paid in THE LANCET of June 4th, 1892. Signor Invernizzi, himself a skilled mechanician and reproducer of the "Beaufort limb," which formed the basis of General Maxwell's charity, has just come back from Massowah reporting on the success with which the poor Ascari have been rehabilitated by the "limb" (an arm or a leg) in question, and strongly advising the Italian Government to adopt the Beaufort system for those of them (300 mutilated ones) who have had to be sent back. Signor Invernizzi has himself, on whose initiative I know not, started a small workshop at Massowah for the manufacture of the Beaufort limb; while to meet the demand in Italy herself the "Arms and Legs Charity" is placing at the disposal of the War Office a certain number of limbs, primarily for those mained soldiers who are of Roman birth or parentage. Amid much that is humiliating to Italy in this disastrous Abyssinian enterprise, the courage, the energy, and the intelligence with which she is retrieving so many of its most tragic sequelæ are in the highest degree reassuring. In rehabilitating its victims she is, in no insignificant fashion, rehabilitating herself.

Cholera on the March.

Our Adriatic and Mediterranean seaports are yielding to panic in view of a cholera invasion. For this overcharged state of public feeling the arrivals from Alexandria are responsible. In that city the European mortality from the disease is said to be thirty-five out of every forty—a mortality still higher among the Arab population, which does not report the cases to the sanitary authorities for fear that the religious rites due to the dead might be officially interdicted. To counteract this motive for reticence the agents of the medical committee exercising surveillance over the districts into which Alexandria is divided are entitled to 10 fr. for every *bonâ-fide* case they report. What accelerated the stampede, and caused the various steamboat services—Lloyd's, the Messageries, the Navigazione Generale, and the Società Russa—to increase the number of boats calling at Alexandria, was the spread of the disease from the lower to the higher strata of society, the rapidly fatal case of the Baroness Richthofen, wife of the German Commissary serving on the Débit Publique, having made a profound and wide impression. Within a few hours of it becoming known all the homeward bound steamers were taken by assault, the fugitives not even inquiring to what port they were destined. This, as I have said, has sufficed to fill the Adriatic and Mediterranean harbour cities with alarm amounting to panic. Fortunately the Public Health Department has, this time at least, proved alive to the danger, and, as already stated, has, since February last, been both vigilant and active in its precautionary measures.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Diseases of the Vena Cava Inferior.

A HIGHLY interesting lecture on Diseases of the Vena Cava Inferior has been delivered by Dr. Schlesinger at a meeting of the Medical Club, in which, after having enumerated the cardinal symptoms, such as œdema of both lower extremities and formation of a typical venous circulation, he referred to those cases in which the disease presents no symptoms and is only ascertained on post-mortem examination. Instances not uncommonly occur where œdema is observed on only one side; the thrombus may be produced by the occlusion of one of the iliac veins and the blood from the lower extremity of the opposite side makes its way to the heart partly by the vena cava and partly by the collateral veins. In these cases of unilateral œdema a diagnosis may be made by an examination of the collateral circulation, for if there are enlarged veins on both sides towards the armpit and the sternum the disease is situated at a point on the cardiac side of the junction of the iliac veins. Among other symptoms Dr. Schlesinger mentioned intumescence of the abdomen up to the costal arch, the occurrence of blood and albumin in the urine, catarrhal diseases of the stomach, bleeding from the intestine, and unilateral varicocele.

The Sense of Taste.

In the Physiological Society Dr. Frankl described last week his experiments on animals whose lingual nerve had been resected. He considered that this nerve contains gustatory fibres for the anterior two-thirds of the tongue and fibres passing into the chorda tympani, the gustatory function of which was discovered long ago, although the method by which the sensations arrive at the brain was unknown. Dr. Frankl believed that they pass with the fifth nerve, for after the resection of Gasser's ganglion agousia of the anterior part of the tongue is established. It has, however, not yet been satisfactorily ascertained whether these fibres are in the second or the third branch; but there are cases in which the sense of taste does not disappear after a lesion of the fifth nerve, and without doubt in these cases the ninth nerve contains fibres for the whole tongue. Section of the glosso-pharyngeal nerve causes atrophy of the gustatory cuplets in the papillæ circumvallatæ, whereas section of the lingual nerve produces atrophy in the anterior part of the tongue.

The Mobility of Abdominal Tumours.

Professor Nothnagel has just published a pamphlet in which he states that the mobility of abdominal tumours is one of their most important physical qualities. Their change of position may be due to the respiratory movement of the diaphragm, to the peristaltic motion of the intestines, to pressure from without, and to their own weight. The organs being below the diaphragm sink downwards with inspiration and rise again during every expiration. In making a differential diagnosis between a tumour of the liver and one of the stomach the possibility of retaining it fixed during expiration points to a tumour of the liver. There is no respiratory mobility of the tumour in pleurisy or emphysema, or in cases of enlarged liver or spleen, conditions by which the contraction of the diaphragm is hindered. The normal liver may also be displaced in the inferior right abdominal region and by palpation may be again restored to its original situation; but it may, on the other hand, be fixed by peritoneal adhesions, so that the immobility of an abdominal tumour is no argument against the existence of displacement of the liver, spleen, or kidney. Tumours of the intestines also show mobility in a high degree, a circumstance which is of great importance in cases where a diagnosis has to be made between new growths and paratyphlitic exudation. Abscesses, aneurysms, and tumours of the pancreas and the retro-peritoneal glands have no mobility.

Pathology of Death from Burns.

Dr. Spiegler has described in the *Medicinische Wochenschrift* the experiments made by him with the view of determining the nature of the virus which is produced in cases of burning and to which the fatal result is directly attributable. He heated the skin of a dead body on copper plates in the hope of obtaining toxic bodies from the burnt skin, but neither the extract nor the distillate had any influence on rabbits. Some years ago Dr. Lustgarten supposed this virus to belong to the group of muscarines, and he was encouraged herein by the fact that a patient suffering from serious burns recovered after an injection of atropine; but, on the other hand, Dr. Spiegler believed that a virus is formed by a disintegration of the albuminous matters in the blood, and he has observed in it numerous particles which are fragments of blood corpuscles. These act as foreign bodies and from them a toxic substance is formed which causes such symptoms as vomiting, spasms, anuria, increased specific gravity of the blood (1065 to 1072), and parenchymatous degeneration.

Mortality in Austria.

The Statistical Commission has just published a report on the death-rates during 1895 in fifty-six of the largest Austrian towns having an aggregate population of 3,536,194 persons. The highest death-rates were registered in Teschen (3·67 per cent.), Prossnitz (3·56 per cent.), Cracow (3·43 per cent.), Stry (3·29 per cent.), and Prague (3·28 per cent.), while the lowest (1·22 per cent.) was in Weinberge. Among each 10,000 of the population there died from small-pox—in Vienna 0·1, in Stanislau 0·9, in Lemberg 1·4, and in Tarnow 6·3; from measles—in Vienna 5·1, in Laibach 11·2, and in Trieste 0·1; from scarlet fever—in Prague 0·3, in Cracow 12·9, in Vienna 3, and in Asch 36·4; from enteric fever—in Tarnopol 7·5, in Lemberg 6·3, in Prague 5·9, in Brünn 3·1, in Salzburg 2·4, in Linz 1·1, in Innsbruck, 0·8, and in Budweis 0·3; from diphtheria—in Marburg 29·7, in Laibach 21·7, in Czernowitz 15·4, in Cracow 12·7, in Linz 9·8, in Brünn 8·2, in Vienna 4·6, in Troppau 3·8, in Salzburg 1·6, and in Karolinenthal 0·5; from phthisis—in Vienna 46·6, in Teschen 73·5, and in Asch 16·7.

PHILADELPHIA.

(FROM OUR OWN CORRESPONDENT.)

Illiterate Immigration.

SOME action is imperatively demanded to check the flood of undesirable immigration. Various measures have been proposed, chief among them being the Stone Bill and the Bartholdt Bill. The former requires consular certification. Each immigrant must under this ruling procure a certificate from a United States Consul, showing that he does not belong to any of the prohibited classes. This would necessitate an increase in the consular service, with a corresponding increased expenditure on the part of the United States. In most cases the Consuls would be dependent on the local government for information relative to the eligibility of the applicant for a certificate, and this is probably the most vulnerable point of the measure. It would be a temptation to the local government to facilitate the departure of the worst element, especially the criminal class, while it would be practically impossible for the young, vigorous, and most desirable class to obtain the necessary certificate. It is likely, too, that efforts at substitution would be made or that the tickets might be bought and sold. The Immigration Restriction League regards the Bartholdt Bill as the most practical. This, known also as the educational test, requires that all male immigrants shall be able to read and write one language. All males between sixteen and sixty years of age unable to comply with this ruling are debarred admission to the country. Parents of persons already residents of the States are exempted, thereby avoiding the separation of families. One powerful argument adduced in favour of this measure is that the steamship companies, knowing ineligible persons will be refused admission to the country, will apply the test themselves, hence preventing their embarkation. This will prevent expenditure on the part of the United States and will spare many a poor soul trouble, expense, and in the end nothing but bitter disappointment. During 1895 about 37,000 people came from Italy. During the first quarter of the present year nearly 20,000 Italian immigrants landed in the United States. It is safe to say that the large majority of them are leaving in order to escape military duty and that very few are actuated by a love for this country. They are not the only undesirable element—Russia, Poland, and Austria-Hungary contribute a large share. These people as a class are illiterate, about 90 per cent. know no trade, and the majority have less than $5 to their name. Since they never readily form a part of the composite American such increments are obviously undesirable. In the case of the Italians, the theory that immigrants seek that part of the country of their adoption whose climatic conditions most nearly approach their native clime does not hold good, for fully 70 per cent. of them settle in New York City or State, a few only go to the South or West, and the balance locate themselves in some of the Eastern States. It is hoped that the Educational Test Bill will successfully close our portals against unworthy immigrants, though they shall ever be opened wide to the intelligent and industrious of any nationality.

Convention of Military Surgeons.

The sixth annual convention of the Association of Military Surgeons of the United States was held in this city on May 12th, 13th, and 14th. Addresses of welcome were delivered by Governor Hastings, who represented the State; by Mayor Warwick, for the city; by Major-General Snowden, on behalf of the National Guard of Pennsylvania; and by Dr. J. M. Da Costa, for the medical profession. The following are some of the topics discussed:—Instruction of the Hospital Corps, by Dr. C. H. Olden, Assistant Surgeon-General, U.S.A.; the Hospital Corps of the National Guard, by Major D. A. Kuyk, First Regiment, Virginia National Guard; Surgeon-General Senn, of the Illinois National Guard, presented a few remarks on a New Bullet Forceps which he had devised for the extraction of the new style of bullets. The proceedings of the second day were held at the University of Pennsylvania. Dr. J. Wm. White, in a clinic at the University Hospital, demonstrated the value of Roentgen rays in surgery. An interesting paper was read by Passed Assistant Surgeon Craig, U.S.A., on the Vitality of the Cholera Spirillum in its Relation to Certain Acid Fruits. A number of experiments were performed to determine the length of time cholera spirilli will live after implantation upon the cut surface of fruits. Cultures were made upon apricots, apples, banana, strawberry, orange, peach, lemon, and melons. It was found that lemon was the most, and water-melon the least, fatal to the germ. On the former fruit five minutes' exposure sufficed to kill them, while they could live several weeks on the melon. A paper on the French Field Sanitary Service and what may be Learned Therefrom was read by Major Havard, Surgeon, U.S.A. At the final session a paper written by Major Paul Brown, entitled "Determination of the Personal Identity of the United States Soldier," was presented. He recommended the introduction of the Bertillon system of measurement as the only reliable means of identification of soldiers. It is used in the French Army. While it has been the practice in this country to record descriptive data of each recruit who enters the army, its use at any future time for the purpose of establishing his personal identity is of questionable value. He said the Bertillon system would be useful in those cases in which an application for a pension is made. The election resulted in the appointment of Medical Director Albert L. Gihon, U.S.A., to the presidency for the ensuing year.

A Case of Prolonged Hypnosis.

A case of prolonged hypnosis, somewhat similar to the one recently on exhibition in London and commented upon in the columns of THE LANCET, is reported from Fort Wayne, Indiana. Santanelli, a professional hypnotiser, put a man to sleep. He is to remain in that state for a week, neither eating nor drinking, constantly being watched by medical students, who will hourly record the temperature, pulse, and respiration. The Humane Society took the matter up and charged Santanelli with assault. He was taken before the justice's court and fined. He refused to awaken his subject and has appealed his case to a higher court.

Chicago: Right of Way granted to Physicians in cases of Obstruction to Traffic.

Some time ago the Chicago Council passed an ordinance granting the physicians the right of way in the streets and over bridges, ahead of processions, parades, fire lines, and other obstructions to ordinary traffic. Upon application and payment of fifty cents the physician is furnished with a special permit and badge. These secure for him the privileges of the ordinance. Ambulances are also given the right of way.

The Diagnosis of Pregnancy by Microscopical Changes in the Urine.

At a meeting of the North-West Medical Society of this city, held in April, Dr. Parkes read a paper with the above title. He spoke of various changes said to take place in the urine of pregnant women, including the kiestine pellicle, upon which at one time a great deal of stress was laid, but which has since been shown to be present in the urine of virgins and even in that of men. He then referred to an investigation pursued by a physician of one of the southern states, who claims to be able to diagnose pregnancy ten days after conception. His method is to add a few drops of the following alkaline solution—viz., ammoniæ murias, aqua ammoniæ, magnesiæ sulphas, of each two parts; aqua, eight parts—to 10 c.c. of urine. This precipitates triple phosphate crystals of the feathery variety. In urine generally these are found in beautiful fern-like or feathery forms, but in the urine of pregnant women they will be found distorted and fractured. Dr. Parkes has examined the urine of more than fifty women, and while he rightly considers the number too small to permit him to make an asseveration he feels that the subject is worthy of further attention. Should it fulfil the claims made for it it would certainly be the most valuable diagnostic sign of early pregnancy; in fact, the only sign.

May 15th.

Obituary.

THOMAS CHARLES STEUART CORRY, M.D. ABERD., M.R.C.S. ENG., L.R.C.P. EDIN.

ANOTHER of the older of the Belfast practitioners, Dr. T. C. S. Corry, has passed away in his seventy-first year. Dr. Corry, who had been in declining health for some years, died on May 20th at his residence, Belfast, to which he had been confined for the past six months. Dr. Corry was the eldest son of Mr. T. C. S. Corry, D.L., of Rockcorry Castle,

Digitized by Google

county Monaghan, where he was born. He studied at the old Belfast Medical School, became M.R.C.S. Eng. in 1846, M.D. Aberd. in 1856, and L.R.C.P. Edin. in 1859. His whole professional life was spent in Belfast, where for a time he was dispensary medical officer during the great cholera epidemic which visited that city about half a century ago. For about twenty-five years he was a member of the board of guardians and only retired in last March. At the end of last year he attained his jubilee as a medical practitioner, when he was presented with an address and testimonial by his friends. Dr. Corry wrote "A Guide to the Scenery and Antiquities of Ireland," which has passed through eight editions; and he was the proprietor of two dioramas of Irish scenery. He also wrote a book of "Irish Lyrics" and "Poems, Sketches," &c. Dr. Corry was a great favourite with the poor, who valued his advice and kindly manner. His funeral was private, but a large number of personal friends attended it.

SURGEON-MAJOR FREDERICK DUCKWORTH, M.D. ST. AND.

AT his residence, Cardiff Castle, Cleveland Town, Bangalore, there died, on the morning of April 28th last, Surgeon-Major F. Duckworth, M.D. (retired list), I.M.S. The deceased gentleman was aged sixty-three years and seven months. He was taken ill about three months previously with Bright's disease, but later he improved. However, a sudden change for the worse taking place, he succumbed despite all that medical aid could do. In 1849 Surgeon-Major Duckworth, at the age of seventeen, commenced his studies at the Madras Medical College. After passing out he was promoted to the rank of assistant apothecary in 1853, and while in that capacity in 1858 he served in the Indian Mutiny, when he was under the orders of Sir Colin Campbell during the siege and capture of Lucknow, for which he received the medal and clasp. In September, 1859, he resigned the Subordinate Medical Service and proceeded to London and thence to Scotland, where, in May, 1860, he took his degree of M.D. in the St. Andrews University. Returning to London in July, 1860, he successfully competed for and obtained a commission in Her Majesty's Indian Medical Service. In May, 1861, he returned to Madras and commenced service as an assistant surgeon. When at Tranquebar in the year 1867, while holding the appointment of civil surgeon and deputy magistrate, he, in conjunction with Mr. Crole of the Indian Civil Service, succeeded in establishing a civil dispensary, known as the Porya Dispensary, by voluntary subscriptions. By this means a sufficient sum of money was raised for the purpose, and the interest accruing therefrom rendered the institution self-supporting, and it stands to this day. In October, 1872, he was promoted to the rank of Surgeon-Major, and in August, 1878, after a meritorious service of twenty-five years in all, he retired on a pension. Since his retirement he had resided in Bangalore. He was the founder of the Duckworth Settlement of the English and Anglo-Indian Colonies and was Vice-President of the Mysore Branch of the British Medical Association. He leaves a widow and a family of five sons and two daughters. His remains were interred in the St. John's Hill Protestant Cemetery.

MEDICAL MAGISTRATE.—Mr. Neville Williams, M.A., M.B. Cantab., M.R.C.S. Eng., has been placed on the commission of the Peace for the borough of Harrogate.

VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.—The annual Court of Governors was held on the 20th inst., when a very satisfactory report and balance sheet was presented. Previously to the adoption of the annual report it was announced that Her Majesty the Queen had forwarded a donation of £50 to help to free the hospital from debt. The Princess Louise had sent £25, and the Duke of York, as chairman at the Festival Dinner, at which a sum of nearly £3000 was subscribed, had contributed £25. 1130 in-patients have been admitted during the past year. The ordinary expenditure during the year amounted to £6529 on account of the hospital and of £1751 on account of the Home at Broadstairs, while the ordinary receipts have been £6110 and £704 respectively, the deficit having to be made up from capital account.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations have been admitted Members of the College, viz.:—

Acland, John Musgrave, L.R.C.P. Lond., University College Hospital.
Adams, William Francis, L.R.C.P. Lond., London Hospital.
Alford, Cyril Wolrige, L.R.C.P. Lond., Middlesex Hospital.
Allen, Walter Henry, L.R.C.P. Lond., Mason College, Queen's and General Hospital, Birmingham.
Anderson, John Sewell, L.R.C.P. Lond., St. Bartholomew's Hospital.
Anstey-Chave, Thomas, L.R.C.P. Lond., St. Bartholomew's Hospital.
Barclay, Herbert Clifford, L.R.C.P. Lond., University of Otago, Dunedin, New Zealand.
Barker, Ernest Marriott, L.R.C.P. Lond, Cambridge University and St. Thomas's Hospital.
Barlow, Thomas William Naylor, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
Behramjee, Dinshah Burjorjee, L.R.C.P. Lond., University of Bombay and Charing-cross Hospital.
Bell, William Blair, L.R.C.P. Lond., King's College Hospital.
Bennetts, Frederick, L.R.C.P. Lond., St. Mary's Hospital.
Benson, John Robinson, L.R.C.P. Lond., King's College Hospital.
Betts, Leonard Bowring, L.R.C.P. Lond., Westminster Hospital.
Bickford, Nicholas Seymour, L.R.C.P. Lond., Charing-cross Hospital.
Black Lewis Potter, L.R.C.P. Lond., University of Cambridge and Middlesex Hospital.
Blagden, John James, L.R.C.P. Lond., St. Bartholomew's Hospital.
Bonney, William Francis Victor, L.R.C.P. Lond., Middlesex Hospital.
Bramwell, Charles, L.R.C.P. Lond., King's College Hospital.
Briggs, John Arthur Oswald, L.R.C.P. Lond., St. Bartholomew's Hospital.
Broadbent, Joseph, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Brock, John, L.R.C.P. Lond., St. Bartholomew's Hospital.
Browne-Mason, Hubert Oliver Browne, L.R.C.P. Lond., St. Mary's Hospital.
Bullmore, Frederick Guy, L.R.C.P. Lond., St. Mary's Hospital.
Cameron, Malcolm, L.R.C.P. Lond., London Hospital.
Cann, Francis John Hughtrede L.R.C.P. Lond., Guy's Hospital.
Clark, Henry Colbatch, L.R.C.P. Lond., Middlesex Hospital.
Clarke, Astley Vavasour, L.R.C.P. Lond., University of Cambridge and Guy's Hospital.
Collis, Edgar Leigh, L.R.C.P. Lond., Oxford University and St. Thomas's Hospital.
Cooper, Harold Merriman, L.R.C.P. Lond., St. George's Hospital.
Coventry, Charles, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester, and Guy's Hospital.
Culmer, Joseph William, L.R.C.P. Lond., Guy's Hospital.
Dashwood, Charles Ewart, L.R.C.P. Lond., University of Cambridge and London Hospital.
Davis, William Lloyd Bowen, L.R.C.P. Lond., Guy's Hospital.
Douglas, Archibald Robert John, L.R.C.P. Lond., St. Bartholomew's Hospital.
Douglas, Stewart Rankin, L.R.C.P. Lond., St. Bartholomew's Hospital.
Draper, Robert Athelstan, L.R.C.P. Lond., University of Cambridge and St. Mary's Hospital.
Druitt, Claud Francis, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
Drury, Edward Guy Du, L.R.C.P. Lond., St. Bartholomew's Hospital.
Edington, George Henry, L.R.C.P. Lond., Royal Infirmary, Glasgow, and King's College Hospital.
Eley, Norman William, L.R.C.P. Lond., Mason College, Queen's and General Hospital, Birmingham.
Ellacombe, Gilbert Henry Wemyss, L.R.C.P. Lond., St. Bartholomew's Hospital.
Ellis, Henry Reginald, L.R.C.P. Lond., St. Bartholomew's Hospital.
Emms, Harry Robert, L.R.C.P. Lond., University College Hospital.
Evans, Harold Ward, L.R.C.P. Lond., London Hospital.
Evans, Robert Jones, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool.
Farndale, John William, L.R.C.P. Lond., Mason College, Queen's and General Hospital, Birmingham.
Fenwick, Samuel Charles Collingwood, L.R.C.P. Lond., St. Mary's Hospital.
Fisk, Edward, L.R.C.P. Lond., Guy's Hospital.
Flory, Cyril Hobson, L.R.C.P. Lond., Guy's Hospital.
Folliott, Edwin, L.R.C.P. Lond., St. Bartholomew's Hospital.
Forman, George Herbert, L.R.C.P. Lond., St. Bartholomew's Hospital.
Foster, John Joseph, L.R.C.P. Lond., Guy's Hospital.
Francisco, Sylvester Agostinho, L.R.C.P. Lond., King's College Hospital
Fry, Arthur Brawnfield, L.R.C.P. Lond., London Hospital.
Fryer, Harold Edgar, L.R.C.P. Lond., St. Mary's Hospital.
Gardiner, John, L.R.C.P. Lond., Middlesex Hospital.
Garner, William Langham, L.R.C.P. Lond., University of Cambridge and Guy's Hospital.
Godwin, Frederick James, L.R.C.P. Lond., Charing-cross Hospital.
Goulden, Herbert Edward, L.R.C.P. Lond., Middlesex Hospital.
Grant, Alexander Smeaton, L.R.C.P. Lond., London Hospital.
Grazebrook, Edwyn Robert, L.R.C.P. Lond., University College and Royal Infirmary, Liverpool, and King's College, Hospital.
Greene, William Adams, L.A.H. Dublin, Ledwich School, Mercers and City of Dublin Hospitals, and London Hospital.

Wright, Samuel Reginald, L.R.C.P. Lond., Charing-cross Hospital.

SOCIETY OF APOTHECARIES OF LONDON, MAY, 1896.—The following candidates passed in the undermentioned subjects:—

Surgery.—F. J. Ayre, St. Mary's Hospital; R. A. Cooper, St. George's Hospital; M. P. Gabe, Middlesex Hospital; D. C. Kemp, University College Hospital; E. S. Langworthy, St. George's Hospital; J. K. McKinlay, Westminster Hospital; M. Orange, Royal Free Hospital; V. A. Settle, Middlesex Hospital; W. V. P. Teague, London Hospital; C. H. Thomas, London Hospital; and G. S. Thompson, St. George's Hospital.

Medicine, Forensic Medicine, and Midwifery.—F. J. Avre, St. Mary's Hospital; E. M. Henwood, Royal Free Hospital; J. W. F. Rait, University College Hospital; and L. St. J. Reilly, London Hospital.

Medicine and Forensic Medicine.—D. C. Kemp, University College Hospital.

Medicine and Midwifery.—A. M. St. J. Wright, Madras.

Medicine.—G. R. Smith, Manchester.

Forensic Medicine and Midwifery.—A. P. Murtz, King's College Hospital.

Forensic Medicine.—C. G. Schultz, St. Mary's Hospital; and V. A. Settle, Middlesex Hospital.

Midwifery.—C. H. Nicholson, Middlesex Hospital.

The diploma of the society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—F. J. Ayre, E. M. Henwood, D. C. Kemp, J. R. McKinlay, C. H. Nicholson, M. Orange, G. R. Smith, and A. M. St. J. Wright.

ROYAL UNIVERSITY OF IRELAND: SPRING EXAMINATIONS, 1896.—The examiners have recommended that the following candidates be adjudged to have passed the under-mentioned examinations:—

M.B., B.Ch., B.A.O. Degrees Examination: Upper Pass.—*Samuel T. Beggs, Queen's College, Belfast; *Stevenson L. Cummins, Queen's College, Cork; *Robert J. Johnstone, B.A., Queen's College, Belfast; *Thomas J. Kenny, B.A., Queen's College, Belfast; James St. L. Kirwan, B.A., Queen's College, Galway, and Catholic University School of Medicine; *Walter S. Smyth, Queen's College, Belfast; William M. H. Spiller, Queen's College, Belfast.

Candidates marked thus (*) may present themselves for the further examinations for honours.

Pass.—Richard Allan, Queen's College, Belfast; Harry F. Browne, Queen's College, Belfast; Robert A. Cunningham, Queen's College, Belfast, and School of Medicine, Edinburgh; Miss L. Dobbs, London School of Medicine for Women; George K. Finlay, Catholic University School of Medicine; Francis T. Heron, Queen's College, Belfast; Benjamin B. Hosford, Queen's College, Cork; Edward J. Liddle, Queen's College, Belfast; George M. B. Liddle, Queen's College, Belfast; Francis J. L. P. M'Kenna, Queen's College, Cork, and Catholic University School of Medicine; William J. Prendergast, Queen's College, Cork; Patrick J. Scannell, Queen's College, Cork; George Scott, Queen's College, Belfast; John V. G. Tighe, Catholic University School of Medicine; and Clara L. Williams, B.A., Royal College of Surgeons.

M.D. Degree Examination.—Emily W. Dickson, M.B., B.Ch., B.A.O., and John H. M'Gee, M.B., B.Ch., B.A.O. (private study).

ROYAL COLLEGE OF SURGEONS IN IRELAND—FELLOWSHIP EXAMINATION.—The following gentlemen having passed the necessary examination have been admitted Fellows of the College:—

J. Davison, G. W. Dawson, A. S. Deane, J. D. McFeely, and J. I. Moore.

FOREIGN UNIVERSITY INTELLIGENCE.—*Halle:* Dr. P. Eisler has received the honorary title of Professor of Anatomy.—*Rostock:* Dr. Barfurth of Iurieff (Dorpat) has been appointed to the chair of Anatomy in succession to Dr. A. von Brunn, deceased.—*St. Petersburg (Military Medical Academy):* Dr. S. Botkin has been appointed Extraordinary Professor of Infectious Diseases and of Bacteriology.—*Philadelphia (Jefferson Medical College):* Dr. W. W. L. Coplin of the Vanderbilt University has been appointed Professor of Pathology and Bacteriology.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—meeting of this society was held on May 20th, Dr. Mutch, esident, being in the chair. Dr. Michie showed the llowing pathological specimens:—(1) Hydronephrotic dney containing two Calculi; (2) a Large Myoma Uteri;) Uterus removed for Pyosalpinx, the tubes being opened)m below; (4) Two Uteri removed for Cancer; (5) Five ches of Colon removed for Cancer; and (6) Portion of Pig's testine showing method of suturing. Dr. Michie then read paper on Gastro-enterostomy. He claimed that the eration relieved pain and prolonged life in cases of cancer the pylorus for a year or two. He deprecated preliminary ashing out of the stomach and abstinence from food by the outh. Washing out should be done through the wound mediately after incising the stomach. The method of iiting the stomach and jejunum was described, suturing ing considered preferable to the use of Murphy's button or her mechanical appliance. Nothing should be given by the outh for the first twenty-four hours, but ordinary diet uld generally be borne on the fourth day. Of six patients erated upon four gained weight and survived for consider-le periods, one died from the operation, and one from the fect of the anæsthetic (ether). The paper was discussed r the President, Dr. Watson, Dr. Tresidder, Dr. Hunter, r. Wood, and Mr. Ringrose.

THE DIFFUSION OF SMALL-POX.—The informa-on coming to hand bears out the opinion that as soon as loucester had, in so far as the bulk of her population is ncerned, secured the protection of vaccination, the idemic of small-pox would abate. The number of new ses of the disease has been for some weeks steadily decreas-g, though even now some hundreds of patients in various ages of the malady are in the hospitals and dwellings of e city. Up to Thursday of last week the cases reported ring the present epidemic period had reached a total of 13. The population of Gloucester is estimated at 42,000 rsons, hence the disease has attacked 1 person in every 25 of e whole place. This rate of 4 per cent. of population is cessive, seeing that for only some six months has the isease been present in the town. Within the last three eeks the cases have totalled in round numbers to 200, a otable quantity still, although far below the records of any ree weeks of the special epidemic period, March and pril. It would be interesting to have the data as to ages persons recently attacked and their condition in reference vaccination. The rush to the vaccination stations as subsided, and with a declining attack-rate is likely ill further to subside. In these circumstances the ty has to fear during the coming summer months a ccession of cases, not only in the unvaccinated class, but so among adults who, having been vaccinated in infancy ily, may fall victims to attacks of a mild nature, hich are no less mischievous in the way of infective ality than the severer cases. Indeed, it may be estioned whether these mild cases do not do more rm, by reason of the fact that they so little in-mmode the sufferers, who accordingly do not always sort to those precautions which are so essential to the fety of others. It is proposed to borrow the sum of 2000 to meet the cost of the exceptional vaccination rangements, though the matter has still to be finally ttled. It would mean four half-yearly rates of ½*d.* in the The cost of vaccination and revaccination, inclusive of mph and other expenses, works out to 1*s.* 10*d.* for each rson operated on. A long discussion has been going in the St. Thomas's rural district on account of leged neglect on the part of the council as to e non-isolation in hospital of a case of small-pox, e council holding the medical attendant to have been blame in the matter. A case of supposed small-x from Westbury, in the Barton Regis rural district, s on admission to hospital in Bristol been diagnosed by . D. S. Davies, the medical officer of health, as one of rpes of an unusual type, and the release from the institu-n of the patient has been ordered. A man suffering from all-pox at Oystermouth has been isolated in the Swansea spital, and has succumbed to the malady. Another case m Mumbles close by has occurred in a household to which me flowers had been consigned from Gloucester. The mber of small-pox cases in hospital at Swansea has declined m 13 a fortnight ago to 6, all mild, on Saturday last. The currence of another case of small-pox at Pontypridd, in the rson of a woman who had slept one night at Gloucester, has placed the authorities in a difficulty because there was no available accommodation in the temporary hospital, which had been designed for one sex only, and was in the occupation of a male patient. The curate of St. Peter's, Derby, has been attacked by small-pox and removed to hospital, the disease having, it is supposed, been contracted whilst he was officiating in some of the low lodging-houses of the borough. At Dalton-in-Furness a second case of small-pox has been sent to the hospital, the patient being the wife of the former patient. She had been in close attendance on her husband.

BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The twentieth annual meeting of the British Medical Temperance Association was held on Thursday, May 21st, at the Wilfrid Lawson Temperance Hotel, Woodford Green, near London. Several members enjoyed a drive through Epping Forest before the meeting. Sir B. W. Richardson presided and Dr. J. J. Ridge, the hon. secretary, read the report which showed that 24 new members and 41 new student associates had been enrolled during the year, making in all 430 members, 96 student associates, and 2 (lay) associates. The official organ, the *Medical Pioneer*, besides being sent to every member, associate, and a large number of subscribers, had been gratuitously distributed to the number of 15,000 to medical men and to medical schools and libraries. This would be extended as funds permitted. Notice was taken of the formation of a Continental Medical Temperance Association on similar lines. The treasurer, Dr. Morton, presented the balance sheet, showing a balance in hand of £22. A prize of £3 offered to medical students for an essay on the Action of Alcohol on the Nervous and Circulatory Systems had been awarded to Mr. J. Phillips, jun., of the Bristol Medical School. The usual temperance breakfast will be given at the annual meeting of the British Medical Association in Carlisle on Thursday, July 30th, in the Central Hotel.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Dr. F. Haycraft Berry, of Watford, Herts, has been presented by the honorary and ordinary members of the Loyal Phœnix Lodge of Oddfellows with a silver epergne.—Dr. Evan Evans has been presented by the successful members of the Llanelly Branch of the St. John Ambulance Class with some silver plate for his instruction on First Aid.—Mr. Jas. G. Boyce, L.R.C.P., L.R.C.S. Irel., of Wotton-under-Edge, has been the recipient of a silver cigarette-case, appropriately inscribed, from the members of the Wotton-under-Edge class of the St. John Ambulance Association as a token of appreciation of his gratuitous services as their lecturer.—Mr. William Hammond, L.R.C.P. Edin., M.R.C.S., of Liskeard, has received a present from the students at Doubledois whom he successfully instructed on First Aid to the injured. The present comprises a revolving bookcase, an armchair, a writing table, a side table, and an illuminated address.—Mr. George John Morgan of Kinnerley, Salop, who is about to leave the district in which he has practised for over twenty years, has been the recipient of an address from the Loyal Argoed Lodge of Oddfellows, to which he was surgeon, and another from friends in the neighbourhood. Mr. Morgan, who is public vaccinator to the Oswestry District Union, has also received a testimonial given under the common seal from the Directors of the Oswestry Incorporation.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of the society was held on Wednesday, May 20th, at 11, Chandos-street, W., the President, Sir James Paget, being in the chair. From the report read by the secretary it appeared that during the year seven new members had been elected and eleven had died and six resigned, leaving 296 at the end of the year. Three widows had been added to the forty-nine on the funds and four had died. The number of orphans receiving assistance had been reduced by one, leaving eight. The receipts available for payments had been £3280 and the grants and expenses had been £3223, including a sum of £452 given at Christmas as a present to the widows and orphans on the books. The funded property had been increased by the purchase of £500 stock, the funded property being now over £95,000. An additional amount—£500—had been received from the executors of Miss Carpue. A grant of £26 under Law 78 was made to a widow. A vote of thanks to the editors of the medical journals for their great kindness in making known the objects of the society was proposed by Mr. Christopher Heath and carried unanimously. The following gentlemen were elected directors to fill the

Digitized by Google

vacancies caused by death and retirement—viz.: Mr. Bennett, Dr. Wilks, Dr. Frederick Roberts, Dr. Sylvester, Mr. Fountaine, Mr. Malcolm Morris, and Mr. Butlin. A vote of thanks, proposed by Mr. Felce and seconded by Mr. Day, was passed to the President, Sir James Paget, for his kindness in presiding at the meeting.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual dinner of the above society was held at the Café Monico on May 20th, the President, Dr. Symons Eccles, being in the chair. Nearly 100 members and guests were present. After the usual loyal toasts the President, in proposing the toast of "The Society," referred to the great success which had been achieved during the current session, especially pointing out that over eighty new members had joined the society and a quarterly medical journal had been successfully started in connexion with the society. The toast of "The Medical Societies" was given by Mr. Bruce Clarke, and acknowledged by Dr. Clement Godson, in the unavoidable absence of the President of the Royal Medical and Chirurgical Society. Dr. Campbell Pope proposed the health of the Cavendish Lecturer, to which Mr. Bryant replied. The "Health of the Guests" was given by Mr. F. Lawrance, and responded to by Sir James Linton, President of the Royal Institute of Painters in Watercolours. The toast of "The President, Dr. Symons Eccles," proposed by Mr. C. B. Keetley in a humorous speech, was received with musical honours. A very successful evening was brought to a close with the toast of "The Officers of the Society," proposed by Mr. H. Menzies, and responded to by the treasurer, Mr. T. G. Alderton, and the secretaries, Mr. L. A. Bidwell and Mr. N. Wood. Both during and after dinner the orchestra of the Brighton Hôtel Métropole performed a selection of music.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Whitsuntide Recess.

THE House of Lords adjourned for the Whitsuntide Recess on Thursday, May 21st, and the House of Commons on the following day. The final sitting of the latter was an all-night one, lasting from 3 P.M. on Thursday until 1.30 P.M. on Friday.

Public Health (Scotland) Bill.

This Bill, after a somewhat severe handling in the House of Lords, has found its way into the House of Commons, where it has been put down for second reading on Monday, June 1st.

The Administration of Workhouse Infirmaries.

In the House of Commons there has been ordered a return showing, in respect of each workhouse and separate workhouse infirmary in England and Wales, the number of persons occupying the wards for the sick on June 1st, 1896 (distinguishing the sick and bedridden from those who are aged and infirm only), the number of paid officers acting as nurses (distinguishing those who, prior to their appointment by the guardians, had received any training in nursing from those who had no training prior to appointment and who are now, as probationers or otherwise, receiving training in nursing), and the period or average period of tenure of office of such officers, excluding those who had not received training in nursing prior to appointment; also the number of pauper inmates who assist in the personal care of the sick, &c., included in the return, distinguishing the number of those who are convalescent patients.

HOUSE OF COMMONS.

THURSDAY, MAY 21ST.

Swine Fever in Ireland.

Mr. Walter Long, in reply to Mr. Kilbride, said that the regulations which prohibit the movement of swine from Ireland into Lancashire except for slaughter and under licence were imposed by the local authority in order to prevent the introduction of swine fever into the county, and it rested with that authority and not with him to say whether, and if so at what date, the regulations might properly be withdrawn. It was unfortunately not the case that Ireland was a non-infected area, 371 outbreaks of swine fever having occurred during the first eighteen weeks of the present year.

Carlow County Infirmary.

Mr. Engledew asked the Chief Secretary to the Lord-Lieutenant of Ireland, with regard to the fact that the Carlow County Infirmary was provided by law for the treatment of the poor and destitute of that county and its expenses provided almost entirely from the public funds of the county, whether he was aware that there were grave doubts in the minds of the ratepayers of the county as to whether that institution treated any of the poor and destitute of the county, and whether the law as to the admission of the patients, the area from which such patients should be admitted, and the manner of admission was carried out, and as to whether the funds of the institution were spent to the best advantage; and whether he would, under these circumstances, consider the necessity of directing that this institution be inspected, as directed by law, by the Local Governme Board inspector, who would also inquire into its general admin tration, and also that all institutions provided for the treatme of the poor and destitute and paid for out of public funds should regularly inspected by a Government official as directed by law.—M Gerald Balfour replied: I am informed that 90 per cent. of the patie relieved in the Carlow Infirmary belong to the poorer classes who treated gratuitously; that the provision of the law as regards admission of patients is habitually complied with; that the goverm believe the funds are expended to the best advantage; and that accounts are periodically published after audit by a manager of Bank of Ireland. As regards the second part of the question I see sufficient ground for applying in this particular case a system of spection which for more than fifty years has fallen into disuse.

The Lee-Metford Rifle.

Mr. Brodrick, Under Secretary of State for War, stated, in reply Mr. Seton-Karr, that no information had been received at the W Office as to the discarding at Bulawayo of the Lee-Metford rifle, b he might say that the question of the bullet was being fully consider

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ADAMS, J., M.D. Aberd., F.R.C.S. Eng., has been appointed Medical Officer for the Workhouse of the Eastbourne Union.

ARCHIBALD, A., M.B., M.S. Aberd., has been appointed Assistant Medical Officer to the Gordon-road Workhouse and the Infirmary of the Parish of Camberwell.

AYMER, JAMES, M.B., C.M. Aberd., has been reappointed Parochial Medical Officer by the Kinneff Parish Council.

BLANDFORD, J. J. G., L.R.C.P. Lond., M.R.C.S., has been appointed Fifth Assistant Medical Officer to the London County Lunatic Asylum at Banstead.

BORTHWICK, THOS., M.D, Ch.M. Edin., has been appointed Medical Officer for the district of Campbelltown South Australia.

BOSTOCK, R. H. F., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Norton Sanitary District of the Malton Union.

BRYAN, JOHN M., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the St. James's (Northampton) Urban Sanitary District.

BUCKELL, F., M.R.C.S., L.S.A., has been reappointed Medical Officer of Health for the Borough of Romsey.

BURGES, R. E., M.D., M.Ch. Irel., has been appointed Medical Officer for Hoole, vice Watson, resigned.

BURNETT, L. B., L.R.C.P. Lond, M.R.C.S., has been appointed Assistant House Surgeon to the Leicester Infirmary.

CALLAGHAN, JOSEPH, L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed *pro tem.* Visiting Justice and Deputy Licensing Magistrate at Windsor, New South Wales.

CALVERLEY, J. E. G., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Metropolitan Hospital, Kingsland-road.

COOLEY, A. G., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed a Medical Officer and Vaccinator for the District of Campbelltown, New South Wales.

CRAWFURD, RAYMOND, M.A., M.D. Oxon., M.R.C.P., has been appointed Physician to Out-patients at the Victoria Hospital for Sick Children, Chelsea.

CROUCH, E. J., M.R.C.S., L.S.A. Lond., has been appointed, *pro tem.*, a Government Medical Officer in Hobart, Tasmania.

FALKENER, L., L.R.C.P. Lond, M.R.C.S., has been appointed Assistant House Physician to the Metropolitan Hospital, Kingsland-road.

FENN, A. C., L.S.A., has been appointed Assistant Medical Officer at the Fever Hospital, Dover.

FINDLAY, W., M.B., C.M. Aberd., has been appointed Medical Officer to the Aberdeen General Dispensary, vice Edmonds, resigned.

FLORY, CYRIL H., M.R.C.S., L.R.C.P., has been appointed House Physician to the Royal Hospital, Sheffield.

FURNIVALL, P., F.R.C.S., L.R.C.P. Lond., has been appointed Assistant Surgeon to the Metropolitan Hospital, Kingsland-road.

HALLAM, H., M.R.C.S., L.R.C.P., has been appointed Junior Assistant House Physician to the Royal Hospital, Sheffield.

HAMPTON, T., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to the Metropolitan Hospital, Kingsland-road.

HOGG, F. S. D., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Bradwell Sanitary District of the Maldon Union.

HUGHES, A. E. P., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer to the Gordon-road Workhouse and the Infirmary of the Parish of Camberwell.

HUSBAND, C., M.R.C.S., has been reappointed Medical Officer of Health for the City of Ripon.

JACKSON, E. S., M.B., C.M. Edin., has been reappointed Medical Officer by the Carnforth District Council.

JOYCE, ALFRED F., M.B., Ch.B Melb., has been appointed Officer of Health for Moorabbin Shire, West Riding, Victoria, Australia.

KAY, J. G., M.B., M.S. Edin., has been appointed Medical Officer for the Tintern Sanitary District of the Chepstow Union and also for the Trellick Sanitary District of the Monmouth Union.

KER, CLAUDE B., M.B., C.M. Edin., has been appointed Medical Superintendent of the Edinburgh City Hospital for Infectious Disease.

LYDDON, RICHARD, M.R.C.S. Eng., L.S.A. Lond., has been appointed Medical Officer of Health to the Urban and Port Sanitary Authorities, Deal, vice A. Bruce Payne, deceased.

MATTHEWS, J. S., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Rural Sanitary Districts of Machynlleth, Pennal, and Scuborycoed.

MORRISON, A. T., M.B., B.Ch. Irel., has been appointed District Medical Officer to the Aylesbury Union.

PHILLIPS, L. C. P., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to the Royal Free Hospital, Gray's-inn-road, London.

POLLARD, GEO. W., M.B. Edin., has been appointed Senior House Surgeon to the Children's Hospital, Myrtle-street, Liverpool.

RAWLINGS, J. D., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed House Physician to the General Lying-in Hospital, York-road, Lambeth.

RANDALL, T. EDWARD, B.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Officer of Health by the Alford Urban District Council.

SHORTRIDGE, T. W., M.D. Brux., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health for Honiton.

SIBLEY, W. K., M.A., M.D. Camb., M.R.C.P. Lond., has been appointed Medical Examiner to the New York Life Insurance Company.

SOYE, E. J., B.Sc. Lond., L.R.C.P., M.R.C.S., has been appointed Assistant House Surgeon to the Metropolitan Hospital, Kingsland-road.

Errata.—In the Appointments column of May 23rd, under the name Woollcombe, "Senior Honorary Surgeon" should read *a Senior*, &c., and the name "Squire" should read *Square*.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BRENTFORD UNION.—Medical Superintendent of Infirmary and Medical Officer of Workhouse and Schools. Salary £250 per annum, with furnished residence in the Infirmary, rations, washing, &c., or £300, with furnished residence, washing, &c. Also Assistant Medical Officer, unmarried. Salary £100 per annum, with furnished apartments in the infirmary, rations, washing, &c. Applications to the Clerk to the Guardians, Union Offices, Isleworth, W.

BOROUGH HOSPITAL, Birkenhead.—Junior House Surgeon. Salary £80 per annum, with board and lodging, but no wines, spirits, or beer.

BUCKS COUNTY LUNATIC ASYLUM.—Assistant Medical Officer, unmarried, at the Asylum at Stone, near Aylesbury. Salary £100 per annum, with board and furnished apartments in the Asylum. Applications to the Clerk, County Hall, Aylesbury.

CANCER HOSPITAL (Free), Fulham-road, S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

CHARING-CROSS HOSPITAL, London.—Surgical Registrar. Salary £40 per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Salary at the rate of £30 per annum, with board and residence.

FISHERTON ASYLUM.—Locum Tenens wanted the second week in June for three weeks. Apply to Dr. Finch, The Asylum, Salisbury.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon to Out-patients (non-resident), for six months. Salary 25 guineas.

LONDON HOSPITAL, Whitechapel, E.—Medical Registrar. Salary £100 per annum. Also Assistant Physician.

MANCHESTER CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham-hill-road.—Honorary Assistant Physician.

PARISH OF CREICH (Sutherland).—Resident Medical Officer and Vaccinator. Salary as Medical Officer, to include medicines, £45 per annum; as Vaccinator, the statutory fees, with an allowance of £5 per year on certain conditions. Applications to Inspector of Poor, Bonar Bridge, Sutherland.

PARISH OF KINCARDINE, Ross.—Resident Medical Officer and Vaccinator. Salary as Medical Officer, to include medicines, £42 10*s.* per annum, as Vaccinator the statutory fees, with an allowance of £5 per year; on certain conditions. Applications to the Chairman of the Parish Council, Ardgay, Ross.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Shoreditch, N.E.—Physician to Out-patients. Applications to the Secretary, Office, 27, Clement's-lane, E.C.

Births, Marriages, and Deaths.

BIRTHS.

DALTON.—On May 26th, at Cranmer House, Cambridge, the wife of J. H. C. Dalton, M.D. Camb., of Trinity College, of a son, born prematurely.

HUME.—On May 24th, the wife of F. N. Hume, Medical Superintendent of the Northern Hospital, Winchmore-hill, N., of a son.

MILTON.—At Port Said, Egypt, the wife of F. R. S. Milton, M.R.C.S., of a son.

PEACHEY.—On May 23rd, at Ballyconnell, co. Cavan, the widow of Allan Thomas Peachey, M.R.C.S., of a son.

PERCEVAL.—On May 23rd, at Whittingham, Preston, the wife of F. Perceval, M.R.C.S., L.R.C.P. Lond., of a daughter.

PRESTON.—On May 8rd, at Kent House, Ryde, I.W., the wife of Lionel L. Preston, M.B. & B.S. Durh., of a daughter.

WILKINSON.—On May 20th, at Leh House, Windsor, the wife of Clement J. Wilkinson, M.R.C.S., of a daughter.

MARRIAGES.

CLUTTON—YOUNG.—On May 21st, at Guildford, H. H. Clutton, F.R.C.S., of Fortland-place, W., to Margaret, third daughter of the late Rev. Canon Young, Rector of Whitnash, Warwickshire.

TUNSTALL—HALLWRIGHT.—On May 2th, at St. Augustine's Church, Edgbaston, John Ogle Tunstall, M.D. Lond., of Ashby House, Sutton Coldfield, to Sibyl Gertrude, younger daughter of Matthew Hallwright, M.R.C.S., Hagley-road, Birmingham.

WYSE—GALLIERS.—On May 19th, at Hanwell Parish Church, by the Rev. Ewart Barter, Richard Wyse, M.A., M.D., Polmont, Stirlingshire, to Anne Sophia, daughter of George Tomkins Galliers, Yan Yean, Australia, late of Herefordshire.

DEATHS.

DUCKWORTH.—On April 28th, at Cardiff Castle, Wheeler-road, Cleveland Town, Bangalore, F. Duckworth, M.D., Surgeon-Major, Retired List, late of Her Majesty's Indian Medical Service, aged 63 years and 7 months. Deeply regretted.

HARKNESS.—On May 22nd, at his residence, Fairlight House, Hampton-hill, Alex Harkness, L.R.C.P. & S. Edin., aged 45 years.

HORTON.—On May 26th, at Bryn Hafod, Bromley, Kent, the residence of his son-in-law, James Horton, M.R.C.S. Lond., of Stepney and Highbury, in his 76th year.

PEACHEY.—On May 22nd, at Ballyconnel, co. Cavan, Allan Thomas Peachey, M.R.C.S., aged 39 years.

WEBB.—On May 20th, 1896, at Rock Bank, Carlton-road, Tunbridge Wells, Kent, Edward Lowe Webb, M.R.C.P. Ed., M.R.C.S. Eng., L.S.A., aged 71 years, late of 9, St. George's-road, London, S.W.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.).

TUESDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (3rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY (4th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Great Northern Central (Gynæcological, 2.30 P.M.).

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.) Gt. Northern Central (2.30 P.M.).

SATURDAY (6th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (1st).—ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Annual General Meeting. Dr. Washbourn: Some Points in Connexion with the Bacteria of the Mouth.

WEDNESDAY (3rd).—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown. Papers:—Mr. A. Doran: Cases of Fibroma of the Ovary and Ovarian Ligament Removed by Operation; with a Series of After-histories of Cases reported in the "Transactions" since 1879.—Dr. J. Phillips: Anterior Colpotomy.—Mr. T. H. Morse: A Case of Impacted Ovarian Dermoid Cyst Removed during the Ninth Month of Pregnancy.

FRIDAY (5th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, W.).—8.30 P.M. Clinical Evening. Dr. Clemow: Rodent Ulcer Excised and Grafted.—Mr. S. Edwards: Curious Anal Affection.—Dr. Abraham and Dr. Dockrell: Skin Affections. And other Cases by Dr. Chapman, Mr. Keetley, Mr. Bidwell, and Mr. Eccles.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (1st).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. Stoker: Chronic Glandular Disease of the Nose and Naso-Pharynx.

WEDNESDAY (3rd).—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Dr. Tooth: Paralysis of the Cranial Nerves.

HOSPITAL FOR CONSUMPTION, &c. (Brompton).—4 P.M. Dr. Wethered: Types of Pulmonary Tuberculosis.

LONDON POST-GRADUATE COURSE.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Acne.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. S. Paget: Surgical Cases.

THURSDAY (4th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Qualitative Tests for Sugar and Acetone in Urine.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. T. Bryant: Clinical Lecture.

THE HOSPITAL FOR SICK CHILDREN (Gt. Ormond-st., W.C.).—4 P.M. Lecture by Dr. Barlow.

VICTORIA HOSPITAL FOR CHILDREN (Tite-street, S.W.).—4 P.M. Dr. Rolleston: Hepatic Disease in Children.

FRIDAY (5th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Actinomycosis and Glanders.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

A DIAGNOSTIC SIGN IN MALARIA.

DR. BOISSON, a French military surgeon, finds that patients suffering from malarial affections, even those of a masked or latent character, always present a peculiar discolouration of the nails. It appears to be independent of the locality in which the malaria was contracted, as he has found it in soldiers both from Tonquin and Madagascar. It appears before the rigor, increasing during the cold stage, and attains its maximum in the middle of the hot stage, after which it gradually diminishes, disappearing towards the close of the sweating stage. This discolouration has been remarked by other observers, but has generally been looked upon as due to circulatory troubles during the cold stage. According to Dr. Boisson, however, it cannot be thus accounted for, as it commences before the cold stage and is most evident later on. It differs also from the livid blue tint due to local asphyxia, being of a gray slate colour, and is due probably to a change in the hæmoglobin of those red corpuscles which are destined to be destroyed during the acute stage. As to the diagnostic value of the sign, he has never failed to find it at the commencement of a malarial attack, and has observed it where no fever occurred in an abortive attack. Once when a patient known to have had malaria was attacked by acute fever with rigors, as the ungual discolouration was absent Dr. Boisson excluded malaria in his diagnosis, and the sequel proved that he was justified in doing so, the affection proving to be an ordinary acute croupous pneumonia. Again, a man with cystitis suffered from intermittent attacks of pyrexia, which Dr. Boisson, in consequence of the presence of discolouration of the nails, was able to diagnose, correctly as it afterwards proved, as due to malaria and not to urinary infection.

L.S.A.—Next week.

"A FEMALE MEMBER OF THE ARMY MEDICAL DEPARTMENT."

To the Editors of THE LANCET.

SIRS,—With reference to "Inquirer's" remark as to the qualifications of Inspector-General James Barry not being traced by him in the "Medical Directory," I have to state that the Chief Clerk in the Army Medical Office, Victoria-street, has to-day informed me that James Barry was duly qualified M.D., and was always so designated in official records. In my earliest letter on this subject in THE LANCET, and again in the preface to my novel "A Modern Sphinx," I alluded to the fact, quoting the experiences of Dr. Thomas Jobson, who qualified in Edinburgh at the same time. I am, Sirs, yours faithfully,

Savage Club, May 21st, 1896. H. ROGERS, Lieutenant-Colonel.

MEDICAL CORONERS AND PROFESSIONAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—I beg to call your attention to the following, and shall be glad if you will publish the same in THE LANCET as I consider it to be a matter especially calling for attention.

In January last, about 2 A.M., I was called to a woman aged sixty years, resident two miles from my house. Upon arrival I found the patient had been dead about half an hour; she had had no occasion to consult a medical man for a period of twelve months previously. The case was reported to the coroner for the lower division of Gloucestershire in the customary manner, and two days later the relatives of the deceased informed me that the coroner had decided not to hold an inquest.

A few days later I received an urgent message to visit a private patient, who had been under my care for over three years. I found him to have all the symptoms of corrosive poisoning, and, in addition, certain bottles containing corrosive fluids were removed from his bedroom. All these I carefully sealed down and still retain in my possession. The patient was afterwards seen by my partner, and, later, by a consulting physician from Clifton, and the above diagnosis maintained; the patient succumbed on the tenth day. The coroner was notified, and on the day of the inquest I was informed by the police officer that another local medical man had been ordered to make a post-mortem examination, the said officer remarking, "Of course, you will attend the inquest." I need hardly mention that I did not do so. At the inquest the medical man was of opinion that death was due to inflammation of the intestines and a verdict was returned in accordance with his evidence.

In commenting on these two cases I may say I did not receive any intimation from the coroner, in fact, my claims were completely ignored by him. In the first case I should like to know, Was the coroner justified in giving a certificate of death without holding an inquest? In the second case, Is it not customary for medical men in attendance to be called to give evidence when an inquest is held? If we are to receive such treatment from a medical coroner what may we expect from lay ones?

Since writing the above my partner has been similarly treated by the same coroner. Yesterday he was called to a man who had been run over by a cart. He found him in a dying condition and he expired almost immediately. An inquest was held to-day, and although he was not summoned my partner was present at the inquiry. A verdict was arrived at without any medical evidence, notwithstanding the fact that a juryman expressed surprise that no medical evidence was forthcoming. The coroner even went so far as to say that the man probably died from internal hæmorrhage, the result of rupture of the liver; and quoted a previous case as an example; whereas my partner, who found fractures of several ribs, the clavicle, and left tibia, is of opinion that the liver was uninjured. The coroner also remarked to the jurymen that had the deceased been found dead in bed he would have granted a necropsy; this is at variance with his behaviour in the first case. Apologising for troubling you, I am, Sirs, yours truly,

Kingswood, May 5th, 1896. R. WILLIAM BRIMACOMBE.

M. U.—The next International Medical Congress will be held at Moscow in 1897. Our correspondent does not sufficiently define the post of the gentleman whose name is desired, but the "Medical Directory" properly searched will give full information.

J. H. W.—We regret not to have had the information handy. The Caledonian and the Sun both offer the facility required; but not, perhaps, without limitations.

"STERILISATION OF MILK."

To the Editors of THE LANCET.

SIRS,—I desire to make a correction in my letter that appeared in THE LANCET on p. 1406, May 16th inst., to this effect: Immersion during five minutes of any steriliser (such as the Cathcart apparatus) in my cooler for hot sterilised milk reduces the temperature of the latter 100° F. (not 50°) say from 200° to 100°, and in ten minutes cools the milk down to the temperature of the water from the main tap; the latter envelops the entire heated surface of the steriliser by direct contact, running in and out of the cooler with great velocity. The water being often down to 45° F., all bacterial development is practically stopped whilst the immersion is continued.

I am, Sirs, yours faithfully,

Waterloo, Liverpool, May 25th, 1896. C. H. LEET, F.R.C.S. Eng.

A. H. C.—Our correspondent's previous communication contained no details. He could not expect us to guess at the causes of quarrel and then comment on them. He hardly needs our encouragement to believe that it is wrong to practise without a diploma. With regard to the offending notice board we can only repeat what we have previously said: In the absence of any precise rules on the matter, the size of a board, the phraseology of its legend, and the duration of its public life must be matters of private taste.

H. A. B.—We are not quite certain whose conduct our correspondent wishes to bring to the notice of the General Medical Council. He should consult his solicitor.

THE TREATMENT OF PLEURITIC EFFUSION.

To the Editors of THE LANCET.

SIRS,—I should be obliged to any of your readers for their advice on the following case. A patient was sent to me in April, recovering from pleurisy with effusion, for which he had been aspirated by his local medical attendant. Finding fluid present I, on April 16th, aspirated, drawing off 150 ounces, but so quickly did it return that on the 24th I again drew off 130 ounces, and on May 7th and 21st 160 and 167 ounces respectively. Locally I have tried blisters, painting with iodine, and a compound ointment of mercury, belladonna, iodine, and camphor, but with no effect. Internally he is taking iodide of potassium and syrupus ferri iodidi. Would frequent aspirations be of use, and what local or internal remedies could I try? I am, Sirs, yours truly,

May 25th, 1896. UBIQUE.

Mr. J. A. Todd.—It is illegal to make a post-mortem examination without permission of the friends of a deceased person or the coroner, as the case may be. This is both common law and equity. The offence is looked upon as "an assault on the body." We fully endorse the letter and spirit of the law. Many people have a religious and sentimental objection to a necropsy on departed relatives or friends, and surely this should receive due recognition. Like other privileges it is liable to abuse. We have reason to believe that it is not an uncommon practice for paupers in workhouses to bequeath their bodies to fellow inmates to prevent their being utilised for dissection under the Anatomy Acts.

R. W. (Epsom).—Any of the instrument makers whose names occur in our advertisement columns could make the appliances at a moderate cost according to instruction. We are not aware that we have ever alluded to any one firm by name.

"THE POISON OF THE PRIMULA."

To the Editors of THE LANCET.

SIRS,—In answer to Dr. Clemesha's letter I may mention that during the last few months I have seen two cases of what may be described as eczema resulting from the presence of the primula family. The face and hands were chiefly affected. In both patients the eyelids of one eye were inflamed and closed, and the fingers presented erythematous eczema with small blebs, some of which were hæmorrhagic. I agree with the writer in thinking that primula poisoning is rather common.

I am, Sirs, yours truly,

HENRY WALDO,

Physician to the Bristol Royal Infirmary, and in charge of

May 26th, 1896. the Department for Skin Diseases.

Mr. R. Lloyd Legate.—So far as we can learn there is no intention of including in this Bill any but poor-law officers as such, and, if so, its provisions will not extend to posts of medical officers of health, whether held by poor-law medical officers or not.

J. D.—Henoch's Diseases of Children can only be obtained by subscribing to the New Sydenham Society. It is, perhaps, the best book on the subject.

ERRATUM.—The price quoted for "Bowlby's Surgical Pathology" in our review of the book on May 23rd is 9s., it should have been 10s. 6d.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Rochdale Observer, Birmingham Post, Kendal Mercury, Wakefield Herald, Oldham Standard, Sussex Daily News, Hereford Times, Ashton-under-Lyne Reporter, Bradford Observer, Newcastle Leader, South Wales Daily News, Pioneer Mail, Dundee Advertiser, North Express, Times of India, Sheffield Telegraph, Sunderland Herald, Bristol Mercury, Western Daily Mercury, North British Daily Mail, Worcester Daily Times, Leeds Mercury, Manchester Courier, Leicester Post, Craven Herald, Scotsman, Builder, Forfar Herald, Bridgwater Independent, Western Mail, Somerset City Herald, Liverpool Daily Post, Architect, Yorkshire Post, Wellingborough News, Sanitary Record, City Press, Brighton Gazette, Spalding Free Press, Yorkshire Evening Post, Elgin Courant, Hertfordshire Mercury, Weekly Free Press and Aberdeen Herald, Reading Mercury, Local Government Chronicle, West Middlesex Standard, Mining Journal, Oswestry and Border Counties Advertiser, Surrey Advertiser, West Middlesex Advertiser, Belfast Evening Telegraph, Local Government Journal, Beverley Recorder, Sunday Times, St. Bartholomew's Hospital Journal, Gloucestershire Chronicle, Dorset County Chronicle, Eastern Counties Times, Glasgow Evening News Durham Chronicle, Lincolnshire Echo, Le Courrier de la Presse, Western Mail, &c., &c.*

The Croonian Lectures:

A CONTRIBUTION TO THE STUDY OF THE BLOOD AND THE CIRCULATION.

Delivered before the Royal College of Physicians of London,

BY GEORGE OLIVER, M.D., F.R.C.P. LOND.

LECTURE I.[1]

Delivered on June 2nd, 1896.

MR. PRESIDENT AND GENTLEMEN,—My first duty is to offer you my sincere thanks for the honour you have done me in asking me to deliver the Croonian Lectures for the present year. The fulfilment of your request has proved not merely a grateful exercise in itself, but a useful incentive to the execution of it. I am, however, painfully sensible of the incompleteness of the results which I propose to submit to your consideration, of the many gaps that remain to be filled in, and of the shortcomings that may be amended by further observation. During the past few years my leisure has been devoted to the physiological study of the circulation and the blood, and during the clinical portion of the year the results attained have been applied to practical ends, so that it has happily fallen to my lot to study side by side, as it were, the physiological and the pathological — the two aspects of one united whole. The subjects chosen may not appear to be closely allied in a physiological or clinical sense. Nevertheless it will be found that the thread of the inquiry has in some degree strung them together. They will be dealt with in the twofold aspects of experimental and applied physiology. The methods of observation and the experimental data will, therefore, precede the application of the physiological positions which they support to "the prevention, control, and cure of diseases"—the practical aim of this course of lectures. According to the injunction imposed by this College on the Croonian lecturer, it would seem that he is expected to hold the balance true between the science and the practice of medicine, and to do his best to further and substantiate the latter by his inquiries into the foundations of the former. The remark is now almost trite and commonplace, but it will bear repetition, that medicine is but a department of physiology. It is practical physiology, or as the Lumleian lecturer of 1892 (Dr. Pye-Smith) tersely and forcibly put it, "pathology is only a chapter of physiology which for convenience we have separated from the rest." Further, practical pathology rises to its highest ideal when it becomes as physiological as are its principles. Research is year by year drifting us upwards to this higher level; and it may now be truly said that the most prominent feature of the practical medicine of to-day is the physiological. In the course of these lectures a few aspects of strictly physiological medicine will come under consideration, such as those relating to exercise, rest, baths, massage, the movement cures, and the animal extracts, in so far as these various agencies affect the circulation and the blood. Some of the physiological modes of treatment to be referred to—such as massage and resistive movements—are distrusted by many, perhaps because they may seem to be somewhat too pretentious and are apt to prove fruitful ground on which charlatanism may flourish. It is to be hoped, however, that further inquiry may shed some light on the physiology of these methods and afford some presumptive evidence of the practical utility of them, so that what in them promises to be useful may not be cast aside through insufficient examination.

This and the following lecture will be devoted to the results of observation on the circulation, and the third and fourth lectures to those referring to the blood.

THE CIRCULATION.

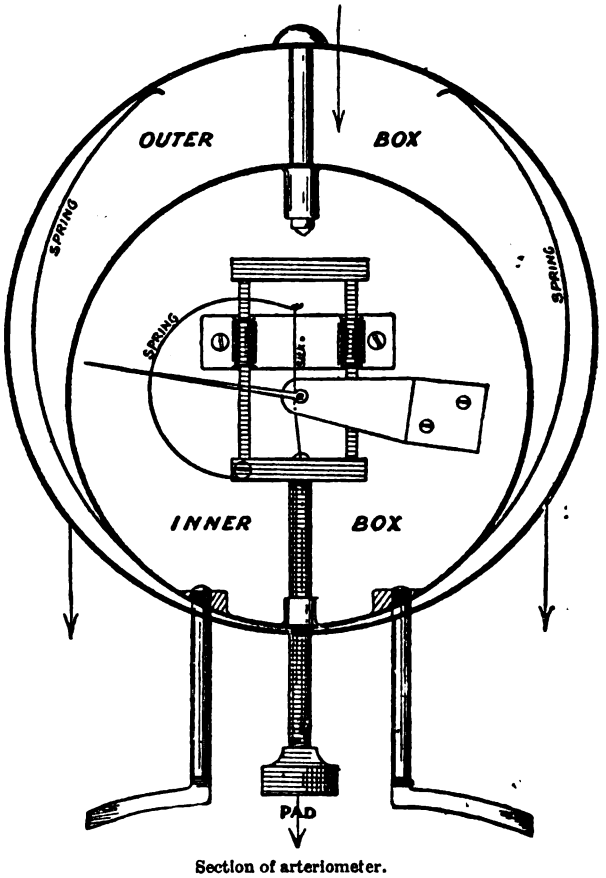
My observations on the circulation in man have been mainly directed to the determination of the calibre of the radial artery and blood pressure with the view of ascertaining the causes—physiological and pathological—which produce variation or which may prevent variation in these important aspects of the pulse. Inasmuch as the diagram of the pulse furnished by the sphygmograph practically leaves these aspects unrecorded or at any rate sheds but an indefinite light upon them, it seemed to me that an inquiry having as its object the direct measurement of them might yield some useful results.

APPARATUS EMPLOYED.

The observations on the pulse were made by means of two instruments — one the arteriometer, so called because it measures the calibre of the artery, and the other the pulse-pressure gauge. The former instrument, however, not merely directly records the calibre, but indirectly indicates the blood pressure; for the calibre is, as a rule, determined by the pressure in the normal condition of the circulation. Hence the arteriometer has been largely relied on in these observations, especially, too, as the varying resistance of the tissues over the artery does not affect the readings obtained by it. The two facts—calibre and pressure—are, however, not always in accord in the pathological field, and for the purpose of discriminating between them the pressure gauge has been found useful. Having recently described these instruments[2] and the mode of using them, it will, perhaps, be unnecessary on this occasion to do more than afford a brief description of the arteriometer. A hydrostatic method of measuring the volume of the limb has also been adopted. In the experiments on animals made in conjunction with Professor Schäfer in the Physiological Laboratory of University College the usual appliances of a well-appointed laboratory were employed.

1. *The arteriometer.*[3]—The mechanism is enclosed in a small circular box (inner box, Fig. 1) which presents below

FIG. 1.



Section of arteriometer.

three stems—one on each side, fixed to the box, carrying the foot-rests, and one between, to which the pad or button is screwed, is free to settle over the site of the artery. This central stem is fixed to a frame, which slides in grooves to maintain the exact vertical direction of the up and down

[1] Lecture II. was delivered on June 4th and Lectures III. and IV. will be delivered on June 9th and 11th.

movement. This movement is communicated to the hand on the dial by a silk thread attached to the lower part of the frame and maintained in a state of uniform tension around the axle by a piece of hair-spring, so that the exact position of the pad in relation to that of the foot-rests is indicated by the hand on the dial. If, now, the two foot-rests are planted by the sides of a piece of rubber tube the pad will settle on it, and the hand on the dial will indicate the position which it has assumed as the starting-point of the measurement to be made, and all that is necessary in order to determine the internal diameter of the tube is some arrangement that will push forward the pad until it closes the tube, when the hand on the dial will travel from its initial position and furnish the required measure. That arrangement is secured by a rod attached to the outer case enclosing the instrument which merely thrusts before it the frame carrying the pad when that case is pushed downwards. As the outer box is pressed forwards you observe that a point is reached when air can no longer be blown through the tube, and in the meanwhile the diameter is recorded on the dial. The outer box serves a most important purpose in making such a delicate measurement as that of the radial calibre. It is separated from the instrument by the intervention of springs which glide towards the rod as it is pressed downwards; so that a uniform pressure is thus maintained on the foot-rests throughout every observation, and the observer cannot unconsciously or in any way modify the reading obtained. The personal equation is thus much more satisfactorily met than it could be even by more elaborate mechanical arrangements. The dial provides for the measurement of four millimetres and is graduated in tenths of a millimetre, and it automatically revolves with the indicator, so that every reading is made from zero and not from a variable part of the scale, as would be the case were the dial to remain fixed. Lastly, it will be obvious that the force used to close the artery always exceeds that of the blood pressure, otherwise the indicator would not travel on the dial.

2. *Volumetric measurement of a limb.*—With the view of determining the difference which may be produced in the volume of a limb by local exercise, by faradaism, by massage, by resistive movements, and by baths, a mode of measurement afforded by the displacement of water has been preferred to that furnished by the plethysmograph or the tape. The following is the method which has been found the most satisfactory. The observations have as a rule been made on the arm. A large trial jar is placed in an overflow basin. After it has been very carefully adjusted to an absolutely horizontal position by a spirit-level it is filled exactly to the brim with tepid water (95° F.), this point being indicated by the correct reflection of a window on the surface. The arm, around which an aniline line has been drawn above the elbow, is immersed until the line is touched all round by the surface of the water. The overflow is then measured before and after the experiment.

THE RESULTS OF OBSERVATION.

Before affording some of the results of observation one or two remarks should be made in regard to the tactile estimation of the lumen of the radial artery which have been suggested by the use of the arteriometer. This instrument has repeatedly yielded me useful service in correcting illusory impressions furnished by the finger in regard to the calibre of the artery under different physiological and pathological conditions. No results have been accepted unless confirmed by two or three separate applications of the instrument, and the corrections it has furnished have often been very considerable. In like manner the tactile estimations of others in regard to the lumen have been tested by it with similar results. The outcome of these observations, therefore, suggests that it is not always such an easy matter as is usually supposed to accurately distinguish between the beat of the pulse and the calibre of the artery. Perhaps this defective discrimination is apt to arise mainly from the ictus so monopolising the tactile appreciation that the observer's estimate of the calibre is liable to be biased by it, and from the difficulty of duly appreciating more than one sensation through the sense of touch at the same time. Observation has shown that the well-trained finger is not so apt to go astray in gauging the lumen when high tension exists as in estimating it when the minimum pressure is much reduced; for then it would seem as if the increased difference between the minimum and maximum pressures is apt to afford an exaggerated impression of the calibre. Examples illustrating this point will be found when reference is made to the effects of exercise, massage, resistive movements, vaso-dilators, and hot baths on the radial pulse.

I. *Physiological Variations of the Radial Pressure and Calibre.*

1. *Posture.*—A change of posture (e.g., from the sitting to the recumbent posture or the reverse) in health is almost invariably accompanied by an immediate and decided alteration in the radial blood pressure and calibre. They both fall as the recumbent posture is assumed; taking the average of observations the variation in the pressure is from 20 to 40 mm. of Hg., and that of the calibre from 0·4 to 0·6 mm. As a rule, when the health is good, and presumably when the vasomotor tone is satisfactory, these postural variations are so well adjusted to the changes of posture that they take place together, without any detectable interval between them and without any oscillatory disturbance intervening; but even in apparent health slight transitional variations, lasting but a few seconds and immediately following the change of posture, are not uncommonly met with before the normal level for the posture assumed is attained. Such transitory intervening variations are probably accounted for by the hydrostatic moment not being compensated for by the dynamic moment, but in a few seconds the compensation is duly adjusted. Moreover, the same fact was repeatedly observed by Mr. Leonard Hill when experimenting on the effects of change of posture on the blood pressure in animals.[4] It probably is the nucleus of that much larger and more prolonged oscillation of the blood pressure produced by change of posture in the subjects of reduced vasomotor tone which will be referred to later. It has been observed that as life advances beyond the middle period the range of postural variation in the radial pressure and calibration become, as a rule, gradually lessened, and may even be abolished. The period when restricted variation may set in is, however, a pretty wide one, and may be said to extend from the fifty-fifth to the seventy-fifth or even eightieth year. How are these normal postural variations produced? It is conceivable that gravity might play an important *rôle* in the distribution of the blood in the different postures in health were there no vasomotor system of nerves or were the function of these nerves in abeyance. But then the effect of gravity on the circulation when the posture is changed would be found to be exactly the reverse of that which obtains in a state of health; for in the erect postures the blood would collect in the capacious venous system within the abdomen and gravitate into the legs, and the vessels in the upper parts of the body would be proportionately reduced, and when the recumbent posture was assumed the blood would become more evenly distributed—the effect of gravity being then neutralised. Under such conditions the radial artery would enlarge in the recumbent and diminish in the erect posture, a result which actually does obtain when the effect of gravity is allowed to manifest itself from failure in the compensating mechanism. Therefore, in normal man the hydrostatic influence of gravity in the erect postures must be counterbalanced, and this compensation is attained by the vasomotor mechanism, and especially by the splanchnic portion of it, a fact which has been so well established by Mr. Leonard Hill.[5] This observer found that in the monkey the compensation is more developed than in rabbits, cats, or dogs, and that it is still more developed in man. In fact, in man it would seem that the adjustment of the vasomotor mechanism to gravity actually amounts to over-compensation, so that when, for example, the erect postures are assumed the vaso-constriction that immediately takes place in the terminal vessels in the splanchnic area and elsewhere is such as to raise the blood pressure throughout the whole arterial system, and when the recumbent posture is resumed that constriction passes away and the arterial fulness subsides. The predominant cause, therefore, of the normal differences observed in the blood pressure and calibre produced by change of posture is vasomotor. Notwithstanding this fact, however, there is evidence to show that gravity does still influence the blood pressure and calibration of the arteries; but the effect of this interference is comparatively insignificant. For example, the subject being recumbent a radial calibre of 1·6 mm. at the level of the arch of the aorta may become 1·7 mm. ten inches below and 1·4 mm. ten inches

[4] The Influence of the Force of Gravity on the Circulation of the Blood, by Leonard Hill, M.B.: Journal of Physiology, 1895.
[5] Op. cit.

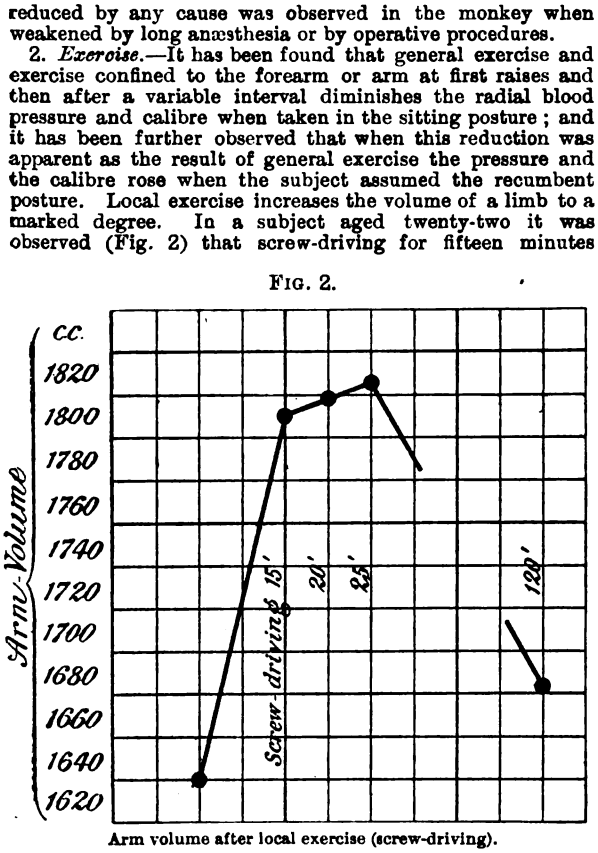
Digitized by Google

above that level. But even this slight influence of gravity is eliminated from the postural measurements by placing the wrist always at the same distance—e.g., four inches—below the level of the aortic arch. When the subject assumes the recumbent posture gravity may be made available for supplying a large amount of additional blood derived from the limbs for circulation in the rest of the body—a fact which may be observed when on putting both legs up and supporting them a radial calibre in the recumbent posture may advance in two minutes from 1·7 mm. to 2·2 mm. Such a position of the limbs may prove useful in certain emergencies, as in syncope.

The agreement between the postural variations observed in normal man and those determined in animals.—Before leaving this part of the subject it should be remarked that the leading results which have been observed in man in regard to the postural variations of the radial pulse have been confirmed by the experiments of Mr. Leonard Hill on monkeys, the two coinciding series of conclusions having been arrived at independently and by totally different methods.[6] For example: (1) the temporary hydrostatic effects frequently observed in man as the immediate result of changing the posture were recorded in the tracings of the blood pressure of the monkey when the animal was turned from the feet down to the horizontal position or *vice versâ*; (2) the postural variations of the blood pressure furnished by healthy subjects were afforded by normal monkeys; and (3) the reversal of these variations found in man when the vasomotor tone is reduced by any cause was observed in the monkey when weakened by long anæsthesia or by operative procedures.

2. *Exercise.*—It has been found that general exercise and exercise confined to the forearm or arm at first raises and then after a variable interval diminishes the radial blood pressure and calibre when taken in the sitting posture; and it has been further observed that when this reduction was apparent as the result of general exercise the pressure and the calibre rose when the subject assumed the recumbent posture. Local exercise increases the volume of a limb to a marked degree. In a subject aged twenty-two it was observed (Fig. 2) that screw-driving for fifteen minutes

FIG. 2.



Arm volume after local exercise (screw-driving).

raised the volumetric measurement of the arm from 1632 c.c. to 1800 c c., and for ten minutes more to 1818 c.c., and that after the expiration of two hours after the cessation of the exercise the volume of the arm still exceeded the initial measure by 88 c.c. How are these effects to be explained? In the first stage of exercise the enlargement of the artery and the increase of the blood pressure are obviously the result of excitation of the heart's action—of the increased discharge of blood into the arteries—and of the active determination of blood towards the muscles; and perhaps also this result is increased by muscular pressure on the peripheral vessels (arterioles and veins). But how is the reduction brought about? It has been repeatedly observed that the diminution of the radial calibre is not in the first instance the result of exhaustion or fatigue, though it undoubtedly becomes still more pronounced when the fatigue-stage of exercise sets in and that it is primarily and intimately associated with muscular effort and therefore is much longer in supervening when exercise is taken on the level than when climbing is attempted, for then it is a comparatively early event. There are probably two prominent causes which induce the reduction of an artery like the radial. In the first place the muscles for example of the arm during exercise, especially local exercise, receive an enormously increased supply of blood which is delivered to them through many branches given off between the axillary artery and the portion of the radial under observation; the blood pressure and the calibre at this point must, therefore, necessarily fall in proportion as the supply of blood to the muscles is increased, the pressure in the arterial tubing of the limb being thus short-circuited as it were throughout. Then, again, in general exercise the most actively employed muscles, such as those of the legs, will probably receive a larger proportionate share of blood; and, furthermore, at a certain stage of the exercise this deviation of the blood downwards will be increased by loss of vasomotor tone permitting gravity to determine some accumulation of blood in the lower parts. Probably all these causes contribute to the radial reduction which occurs in the active postures at a certain stage of general exercise, as in walking, and especially in climbing; but in all probability the predominant cause is the active derivation of blood into the capacious periphery of the circulation located in the muscles. This position is supported by the fact that an artery like the temporal, which is not supplied to muscles actively employed in exercise, remains persistently distended throughout a long-continued muscular effort, such as that of climbing for many hours[7]; and by the observation that the radial artery of one arm slung at rest during moderate exercise is not reduced, while that of the free arm is reduced.[8] Diminution of vasomotor tone in the second stage of exercise is probably the cause of the rise of the radial pressure and calibre observed in the passive posture (recumbency) when gravitation ceases to influence the circulation. Why should the volume of the exercised limb increase? The rapid accession of blood is obviously the cause of the immediate enlargement; but though this may be accounted for by the turgescence of the vessels which accompanies muscular contraction, I think it is somewhat doubtful if the persistence of the swelling for several hours after the cessation of all muscular action can be thus satisfactorily explained, for surely such a distension of the vessels should cease pretty soon after the muscles become relaxed, and the enlargement due to it alone would, therefore, quickly pass away. Does not the continuance of the swelling point to the supervention of some other event beyond the mere temporary distension of the vessels, such as the exudation of fluid from the blood into the substance of the muscle? There is some corroboration in support of such a view in the results of some experiments performed by Dr. Lazarus Barlow in the pathological laboratory at Cambridge in 1894 on the effects of Variations in the Volume of the Blood upon the Specific Gravity of Blood and of Muscle.[9] That observer increased the volume of the blood in two different ways: in one he anæmiated one or more limbs by the tight application of Esmarch's elastic bandages and thus forced whatever fluid, blood as well as lymph, that was in them into the general circulation; and in the other method he injected salt solution into the blood. The specific gravity of the blood and of the blood-plasma was taken by Roy's method, and that of the muscles by a modification of that method before and after the volume of the blood had been increased. The results obtained were a rise of the specific gravity of the blood and of the blood-plasma, and an invariable fall in the specific gravity of the muscle, the rise and fall being rapidly induced, the larger portion of them occurring within the first half hour. This observer, therefore, concludes that when the volume of the blood is increased the muscles take up water which is derived from the blood. In exercise the volume of blood circulating through the muscles is in all probability increased to a much higher degree than obtained in these experiments,

and therefore a most favourable condition exists for the rapid transudation of watery fluid from the blood to the muscular tissues. During the actual muscular contraction a portion of this exuded fluid is no doubt driven onward into the lymphatics by the pressure brought to bear on the lymphatic spaces by the contracting muscular fibres; but it is quite conceivable that a large quantity of that fluid may remain in the muscles for a considerable time after all muscular action has ceased. This position is furthermore corroborated by the changes observed in the blood as the result of exercise. These will be referred to in the fourth lecture. This matter may seem to possess a merely theoretical interest; but it is conceivable that it may have a somewhat important practical side which will be touched upon when an attempt is made to explain some of the beneficial effects to be obtained from the movement cures.

3. *Digestion.*—During the first hour after a full meal as a rule the radial pressure and calibre fall very considerably in the sitting and rise proportionately in the recumbent posture. The leading cause of this alteration on the radial pulse would seem to be the increased flow of blood to the digestive tract and the large vascular glands within the abdomen, which in the erect postures reduces the blood pressure in the upper half of the body mainly through the agency of gravity, but ceases to do so in recumbency, because in that posture gravity fails to operate. Mr. Leonard Hill by his valuable experiments on animals has demonstrated that the splanchnic vasomotor mechanism occupies an all-important place in compensating for the simple hydrostatic effects of gravity on the circulation of the blood produced by changes of posture, and that where the perfection of this compensatory mechanism is impaired the influence of gravity on the systemic circulation becomes of vital importance, so that in the feet-down position the blood drains into the abdominal veins and recedes from the upper portions of the body.[10] It would seem that during the digestive act a comparatively transient impairment of the splanchnic vasomotor mechanism—probably more pronounced in some individuals than in others—does take place; but in healthy subjects it is quicky followed by complete compensation—in fact, by over-compensation—for the primary fall in the arterial pressure is succeeded by a rapidly developed rise beyond the degree recorded before the meal, and this rise, which, corresponds with the acme of fulness of the systemic arteries, gradually subsides before the next meal is taken.

4. *Fatigue.*—The ordinary effects of change of posture in the healthy subject on the radial pressure and calibre have been described—namely, an increase of both in the sitting and a decrease in the recumbent posture. Every now and then, however, these measurements are observed to be reversed; and it has been found that fatigue is a common cause of this departure from the strictly normal formula of the postural measurement of the pulse. Repeated observation has shown that the essential fact in the transitory conditions of tiredness or fatigue is a diminution of the vasomotor compensation which at other times perfectly counteracts the hydrostatic effects of gravity on the distribution of the blood. In health this is but a passing phase of vasomotor inadequacy which finds restoration in the recumbent posture. It is, however, the embryo as it were of that persistent impairment of vascular accommodation which may be observed and measured by the arteriometer in many ailments to be referred to later.

5. *Menstruation.*—Throughout the menstrual period it has been repeatedly observed that the calibre of the arteries, as exemplified by the radial, ceases to respond to change of posture. Later it will be shown that this is a sign of arterial tension. Probably, therefore, during menstruation vaso-constriction invades the arteries and extends to those of middle size like the radial. This transitory phase of arterial contraction resembles that which is quite common for limited periods in the gouty and that which always accompanies attacks of *migraine*.

Variations of arterial tension from the physiological aspect.—The fundamental fact in regard to the circulation in normal subjects is that it is a system of elastic tubing which is never at any one time and in all parts filled with the circulating fluid, so that there always exists in every part a pretty wide margin for the production of the extremes of variation of pressure consistent with health, which may be induced by alterations either in the volume of the fluid or in the size of the tubing. In the central parts of this system it is highly probable that the blood pressure varies within much narrower limits than it does in the peripheral arterial tubes, in which it may be considerably increased or diminished according to the ebb and flow of the activity of organs, and that consequently the volume of the blood and the size of the peripheral arteries are continually varying in different parts of the body. Inasmuch as the functional activity of any one part affects not merely its own blood-supply, but influences that of every other part, the peripheral blood pressure must be an ever fluctuating quantity—within certain limits. The condition of the vasomotor mechanism largely determines the order which the fluctuations follow; and inasmuch as the most delicate test of the integrity or otherwise of that mechanism is afforded by the effects produced on the radial calibre and pressure by change of posture, that test has been adopted throughout this inquiry.

[10] Op. cit.

II.—*Pathological Variations of Radial Measurement.*

Observation has shown that when the radial calibre either varies repeatedly in the reverse order to that which obtains in health or persistently ceases to vary on change of posture some pathological condition may be inferred to exist; and that such deviations from the normal formula of radial measurement when persistent group together certain morbid conditions.

1. *The postural variation is reversed.*—It has been shown that in health the reversed postural formula of radial calibration is met with as the result of the digestive act, of exercise, and of fatigue. In all these instances there exists one common cause accounting for the reduction of the radial calibre in the erect postures—namely, diversion of blood—in digestion to the abdominal organs, in exercise to the muscles, and in fatigue to the lower parts of the body from impairment of vasomotor tone. In health this is but a passing phase of the distribution of blood. In disease it is also due to a diversion of blood, which is, however, of a less or more persistent character. The blood abstracted from the arterial side of the circulation in the erect postures gravitates into the splanchnic area and (to a less degree) into the veins of the legs. So that all the cases thus grouped together are characterised by impairment of the vasomotor mechanism. Mr. Leonard Hill has demonstrated that when paralysis of the splanchnic vaso-constrictors is brought about in animals, as by anæsthetics or by operative procedures, pressure applied to the abdomen by means of a bandage at once restores the blood pressure so long as the heart is normal or is not too weak to effectually propel the increased supply of blood furnished by the compression of the abdominal veins.[11] It has been repeatedly observed that when the radial calibre is reduced in the sitting posture the application of abdominal pressure, while the arteriometer remains *in situ*, will as quickly raise it to what it attains in recumbency as was the blood pressure restored by the same procedure in Mr. Hill's experiments. Furthermore, the same result is attained, as has been frequently proved, by making the subject in the recumbent posture execute a series of from six or more slow, prolonged, and deep inspirations after forced expiration, while the abdominal muscles are contracted as in the Italian method of singing—a form of respiratory gymnastics which apparently aspirates the blood to the heart, effectually compresses the abdominal veins, and induces a stronger stroke of the heart and an increased transference of blood from the venous to the arterial side of the circulation.[12] The following is an example of this restoration of the normal balance of the blood-supply to the arteries by this means:—

—	Radial calibre.	
	Sitting.	Recumbent.
Before forced respiration	1·4 mm.	1·9 mm.
After six forced respirations	1·9 mm.	1·4 mm.

These observations indicate that when the vasomotor mechanism is impaired, as is shown by the reduction of the radial pulse in the upright postures, the blood unduly collects in the splanchnic area; in fact, a portion of the

[11] Op. cit.

[12] This procedure as a mode of treatment was brought to my notice by Dr. Edward Blake, who has, he informs me, successfully applied it for some years past in the treatment of dilated and weak hearts.

Digitized by Google

blood is thus abstracted from the arterial side of the circulation and is transferred to the venous side. What ailments are mainly characterised by the presence of this radial sign of a damaged state of the vasomotor mechanism? Observation has shown that it is commonly met with in anæmia, in all the various forms of nervous exhaustion, in the febrile state, in convalescents, and in cardiac incompetency. It would seem that the underlying pathological condition is asthenia, and especially asthenia which springs from impoverishment of the blood or from denutrition of the nerve-centres. These are the forms of asthenia in which the reversed radial measurement is observed most frequently, and they ramify through a large group of cases, and, therefore, embrace a considerable section of clinical observation. It has been found that this radial sign of asthenia is pretty constantly present in that form of nervous debility which now passes under the name of neurasthenia and in closely allied ailments of the nervous system. It is, therefore, probable that in cases of this type a paretic condition of the vasomotor constrictors is a prominent pathological feature, which may, moreover, in a great measure account for many of the symptoms which such cases manifest. In the erect postures the reduced supply of blood to the arteries which are distributed to the upper portions of the body, and the drain of blood into the lower parts, and especially into the abdominal area, will undoubtedly favour the development of cerebral anæmia and the occurrence of various abdominal disturbances and ailments to which the sufferers of denutrition of the nerve-centres are so liable. Influenza during the past seven years has developed a large crop of these cases; and it has been an easy matter to trace the debilitating effects of this disease on the mental and physical system, so ably pourtrayed by Sir Dyce Duckworth in his recently delivered Lumleian Lectures, to vasomotor paresis the result of impaired nutrition of the nerve-centre. The gravitation of blood into the splanchnic area in anæmia and neurasthenia will doubtless foster the prevalence of digestive and intestinal disorders. In cases of vasomotor inadequacy it is not at all an uncommon observation to find the liver slightly enlarged and with a tender margin. Thirteen years ago Germain Sée[13] recorded the proneness of neurasthenic subjects to dilatation of the stomach; and in more recent years the same clinical association has been pointed out by Dujardin-Beaumetz,[14] Champagnac,[15] and quite recently by A. S. Eccles.[16] The last observer has, moreover, shown that "a large proportion of the gastro-intestinal cases successfully treated by the 'rest-cure' have been associated with neurasthenia."[17] This leads me to say a word on the value of recumbent rest in the treatment of all cases in which the maximum radial calibre is habitually present in the recumbent posture. The augmented supply of arterial blood to the tissues, and especially to the impoverished nerve-centres, which obtains in these cases when the recumbent posture is assumed, should prove remedial, and the results of observation have distinctly shown that this is the case. In exceptional cases of this type absolute rest should be adopted for a time, but when exercise is feasible the proper adjustment of it tends to accentuate the restorative value of recumbency which is enjoined between whiles. Inasmuch as the arteriometer has shown that in these cases of damaged compensation the sitting posture maintains the mal-distribution of blood, which perpetuates many of the symptoms, it is obvious that that posture does not secure physiological rest at all; it should, therefore, be abolished for a time and should be replaced by recumbency, in which the blood is fully and normally distributed, or it should be alternated with exercise under strict rule. This direction may seem to be too trivial to deserve notice. Having, however, so frequently proved the value of this physiological means of adjustment of the circulation in cases of vasomotor inadequacy I trust this passing reference to it may not be out of place.

2. *The calibre is uniform or is greatly restricted in posture.*—In health the radial calibre is very rarely free from variation on change of posture; and should such a condition be observed it is, moreover, quite transitory. In clinical observation, on the other hand, an unvarying radial calibre is frequently to be met with, and when persistent it always signifies some important pathological condition. It may come and go or it may be persistent.

(1) *Temporary uniformity* is often met with as a result of vasomotor contraction and the consequent rise of arterial tension. Good examples are afforded by migraine and by passing gouty states. When the contraction is chiefly peripheral or terminal the radial blood pressure rises; but when it involves the radial itself the blood pressure within the artery generally falls, but rises in the central arteries. Observation has shown that in chronic gout the radial calibre may be large and uniform with raised blood pressure, or it may be small and uniform with a normal or subnormal blood pressure. When the gouty state is relieved and there is no arterio-sclerosis present the uniformity of the calibration in both classes of cases gives place to variation and the blood pressure in the first falls, while in the second it may rise. Transitory attacks of high arterial tension of apparently peripheral origin (probably constrictive in nature) are of frequent occurrence in the elderly;[18] and it has been observed that throughout each attack the radial calibre becomes fixed, while in the intervals postural variation reappears. The subjects of such attacks, though they may themselves be free from the ordinary manifestations of gout, frequently belong to families in which a history of true gout exists. It has been observed that in transitory tension a rise in radial blood pressure of a little over the normal variation for posture (30 mm. of Hg.) will determine postural uniformity in the calibre and that when this excess disappears the arterial wall will once more respond to change of posture.

(2) *Persistent uniformity* characterises an important group of diseases. The predominant cause is not, as in temporary uniformity, tonic muscular constriction, but a structural change in the arterial wall. The blood pressure may or may not be increased. Observation has shown that this invariability is exceedingly common in arterio-sclerosis, either alone or accompanying chronic interstitial nephritis, angina pectoris, or chronic gout, and in acquired syphilis. In arterio-sclerosis it has been observed that even the presence of a very marked degree of anæmia, as may be met with in chronic Bright's disease, does not prevent the postural invariability of the calibre from manifesting itself, even though it is found that in such cases the blood pressure is higher in the recumbent than it is in the sitting posture. The size of the lumen of the artery is largely determined by the blood pressure; but in all cases after a time it diminishes very considerably. Acquired syphilis differs from arterio-sclerosis, however, in the fact that the calibre shrinks to a far greater degree, especially after the lapse of several years from the primary infection, and especially, too, when the disease is producing its secondary and tertiary manifestations; a reduction to one-half of the measurement, which it may again acquire after treatment by mercury, has not infrequently been observed.

III. *Radial Measurement in Experimental Physiology.*

The arteriometer has afforded useful aid in several lines of inquiry. I will illustrate this position by describing the effects on the pulse of anæsthetics, vaso-dilators, the animal extracts, massage, resistive movements, electricity, and baths.

Anæsthetics.—A number of observations made on the effects of anæsthetics on the radial calibre has shown (Fig. 3) that ether increases while chloroform reduces it. Nitrous oxide occupies an intermediate position, causing a slight rise which may be followed by a fall; the fall, however, fails to be detected when the gas is inhaled along with oxygen.[19] Oxygen, like ether, enlarges the calibre. The A.C.E. mixture reduces it, but to a less degree than chloroform. Mr. Leonard Hill has shown experimentally that the two anæsthetics, ether and chloroform, differ very markedly in their effect on the vasomotor mechanism. While chloroform rapidly paralyses compensation and damages the heart ether does not in moderate amounts impair the vasomotor mechanism, and only does so very gradually and to a limited degree when pushed in enormous amounts, and it, moreover, stimulates and maintains the heart's action.[20] This difference in the physiological action of these anæsthetics suffices to account for the reduction of the radial artery by chloroform

on the one hand and for the augmentation of it by ether on the other. The practical application of these observations will be obvious. The position of the abdomen in relation to the head must be of much greater importance in chloroform than in ether anæsthesia; for in the former the splanchnic drain will be much increased in the vertical posture, or even when the head and shoulders are raised somewhat above the abdomen, while in the latter, unless the ether has been administered in large quantity or for a prolonged period, there is no undue collection of blood in the

FIG. 3.

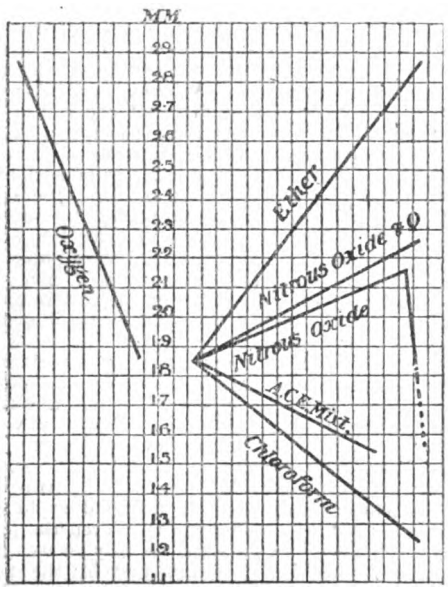

Diagram showing the average results of observations on the effects of anæsthetics on the radial calibre.

abdominal area. It has been shown that deep inspiration and also that abdominal compression reduce the veins when containing an excess of blood; hence the value of artificial respiration and of pressure over the abdomen when death is threatened by vasomotor paralysis during chloroform anæsthesia, and hence also the utility of that most favourable sign, the act of vomiting, which is a most efficient mode of abdominal compression.

Vaso-dilators.—Some few observations with the arteriometer have indicated that the nitrites and nitro-glycerine rapidly lower the radial blood pressure and calibre. Fig. 4 shows that the action of $\frac{1}{100}$th grain of nitro-glycerine is rapid and decisive and lasts but a short time; in this case not beyond an hour. Why is the calibre of the artery reduced? This result may be explained by the lessening of the blood pressure within the artery consequent on dilatation of the peripheral vessels. This fact has been proved by perfusion through excised organs, and was ably illustrated by Professor Leech in the Croonian Lectures of 1893. Inasmuch as the radial artery is but a conduit between the heart and the peripheral vessels, the blood pressure within it necessarily falls as these dilate, and the calibre of it is thus correspondingly reduced. From the observations made it would, however, seem that the vaso-dilatory action extends to the splanchnic area, so that in the erect posture a large amount of blood gathers in the capacious veins within the abdomen and largely contributes to the reduction of the systemic arteries. This position is supported by two facts: the enormous rise of the radial calibre when the subject assumes the recumbent posture and the production of a similar rise in the sitting posture by the application of pressure to the abdomen. In the Bradshaw Lecture delivered before this College in November last Dr. Bradbury ably supported the claim of the solid organic nitrates (erythrol tetranitrate and mannitol hexanitrate[21]) as vaso-dilators of more enduring action than those in present use, and therefore more likely to prove useful than they in the necessarily somewhat continued treatment of several morbid conditions associated with increased peripheral resistance. Dr. Bradbury showed as the result of perfusion experiments on excised organs and of sphygmographic observation that the vaso-dilator action of these substances was, though less energetic and slower to manifest itself, very much more prolonged than that of the nitrites and nitro-glycerine. With the view of comparing the action of the

solid organic nitrates on the arteries by the side of that of nitro-glycerine some observations were made with erythrol tetranitrate on the same subject[22] which provided the data recorded in Fig. 5, and the results obtained, though obtained by totally different methods, entirely support Dr. Bradbury's conclusions. It has been shown that the vaso-dilator effect of nitro-glycerine is already pronounced within fifteen minutes (Fig. 4); but it requires the lapse of sixty minutes

before it becomes established after swallowing one grain of erythrol tetranitrate, when, indeed, that of nitro-glycerine has completely passed away; and, furthermore, after the lapse of three and a half hours it is still well maintained with some probability of continuing some hours longer, though no later observation was made. The relative vaso-dilator activity of nitro-glycerine and erythrol tetranitrate are expressed in the degree of reversals of the postural

[21] These substances are obtained by nitrating the alcohols or corresponding compounds by means of a mixture of nitric and sulphuric acids at a low temperature.

measurements. The reduction of the blood pressure—especially of the minimum pressure—produced by the vaso-dilators affords to the finger an illusory impression of enlargement of the artery.

Professor Leech, in his second Croonian Lecture (1893), in referring to this point, says: "How are we to account for the markedly greater distinctness of the pulse which is so often noted after nitrites and for the increased height in the upstroke (the so-called 'percussion wave') of the tracing which is almost invariably seen after small doses of the nitrites?" He refers this change in the pulse to two causes—namely: (1) dilatation of the arterioles, which induces a more complete collapse of the artery and an increased difference between its systole and diastole both to the finger and in the tracing; and (2) relaxation of the artery itself. "The difference between the calibre of the artery in systole and diastole being augmented it is felt to be more distinct and more full." This explanation accords with the results of my observations, only I am led by them to regard arteriolar dilatation as sufficient to account for all the facts of the case. The vaso-dilators afford the most satisfactory experimental evidence of the manner in which the postural formula is reversed in various pathological conditions, all characterised by a reduction of vasomotor tone which impairs compensation for gravity.

Remarks
UPON
THE PRESENT SYSTEM OF MEDICAL EXAMINATIONS.[1]

BY T. PRIDGIN TEALE, F.R.C.S.ENG., F.R.S.,
CONSULTING SURGEON TO THE LEEDS GENERAL INFIRMARY.

"That the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it are not only unjust to the student, but damaging to medical education; therefore, that the time has arrived when the General Medical Council should consider (*a*) how far examinations and the occasions of rejections can be reduced in number; (*b*) how far, whilst maintaining effective examinations in those subjects which it is essential that every medical man should 'know' and 'retain the knowledge of,' it is possible to withdraw from the sphere of public examination several other subjects which it is desirable that every medical man should 'know about,' but with the details of which he need not permanently burden his mind, the 'bird's-eye survey' of such subjects being ensured by compulsory short courses of lectures with class examinations certified by the teacher."

GENTLEMEN,—The motion which stands in my name is substantially the same which was proposed at the last session of Council, the discussion of which was postponed at my request. Since the motion was placed upon the programme of business two events have happened which go some way to justify the course taken. Two subjects, which would have been occasions of rejections, have been withdrawn from their scheme by the most important examining body in the United Kingdom, the Conjoint Board for England. These subjects are the examination in elementary anatomy at the end of the first year of study and the proposed examination in pharmacology as a new and separate subject for rejections in the final examination. In proposing such a motion I am undertaking a serious responsibility, not only in raising the question at all, but also in occupying the time of the Council with what I have to say. As to the latter point members of Council—and not least the older members—will bear me out when I claim to have occupied during my twenty years of service here but little time in making speeches. On the former I wish to state views which have been forcing themselves upon my mind more and more, silence about which on my part might be blameworthy, and for the utterance of which no fit opportunity has heretofore seemed to have arisen. During the past twenty years the Council has added to the subjects which have of necessity to be examined upon, has doubled the number of examinations which have to be passed, has by its visitations and inspections increased the stringency of examinations—i.e., has caused a higher percentage of rejections—and, finally, has added one year to the medical course. All has been done with this object—that the medical practitioner may be turned out a more perfect article and that incompetent men may be excluded from our profession You may rightly ask on what evidence such opinions as are expressed in the motion are based. They are based upon: 1. The statistics of rejections as reported to this Council. 2. The fallibility of examination in respect of (*a*) the element of chance; (*b*) the inevitable hurry with which a great portion of our examinations have to be conducted; and (*c*) the unsuitable misguiding questions which appear in examination papers. 3. The interference with clinical work. 4. The probable working out in practice of the five years' course. 5. The cost to parents of multiplied rejections.

Let us take the first point, "the statistics of rejections," and inquire what lessons they teach and see what has been the attitude of the Council towards this question. On May 25th, 1876 (Minutes XIII., p. 135), it was moved by Dr. Andrew Wood and seconded by Mr. Quain and agreed to: "That the table showing results of examinations for degrees, diplomas, and licences granted in 1875 by the bodies in Schedule A of the Medical Act be referred to a committee to consider the table of results with reference to so large a number of rejections and to report thereon." And what was the large number of rejections that moved the concern of the Council? It was this, that the percentage of rejections in the final examination had risen from 12·4 per cent. in 1862 to 22·2 per cent. in 1876 and had become practically double. At the present time, twenty years later, they are 38 per cent. The committee reported on June 5th (Minutes XIII., p. 261) suggesting that the executive committee should obtain information from the licensing bodies on several points bearing upon the question. The executive committee on July 7th (Minutes XIII., p. 341) addressed a letter to the several licensing bodies on the results of professional examinations. On March 9th, 1877 (Minutes XIV., p. 277), Professor Humphry was requested by the executive committee to report upon the answers from the licensing bodies. This report (Minutes XIV., p. 64) was presented to the Council on May 16th, 1877. As an outcome of this report the Council "recommended" that there should be three professional examinations (Minutes XIV., p. 99) and that a committee should be appointed (p. 110) to consider the subjects of professional examinations to be required and the limitations of the range of the subjects by schedule. Again, in 1880, after a resolution of the Council to resume the visitation of examinations, it was moved by Professor Humphry and seconded by Dr. Rolleston and agreed to: "That it be a direction to the executive committee to instruct visitors to inquire into the causes of the rejections which appear in the annual returns" (Minutes XXII., p. 152). The percentage of rejections at the final examination had in that year risen to 28 per cent. Lastly, on May 24th, 1883 (Minutes XXX., p. 52), a resolution, moved by Dr. Heron Watson and seconded by Dr. Bruce, was carried: "That the tables of rejections of the programme, May 23rd, 1895, be referred to the Examination Committee with a view to prepare a statistical statement of the percentages reported in previous years as well as those since the passing of the Medical Act, 1886," &c. The primary object of this resolution was to find an explanation of the variability of the percentage of rejection in the several examinations. The outcome of the investigation by the Examination Committee was practically *nil*, except in one respect. A most striking table of the rejections reported to the Council from the year 1861 to the year 1892 was drawn up by our registrar, which to my mind speaks volumes, although its message seemed to fall on deaf ears in the committee. What do we find in this document? Taking final examinations only, in 1861, rejections 12·4; in 1870, 22·2; in 1880, 28·9; and in 1892, 38·9. But there is another point in all this. In 1861, with very few exceptions, the licensing boards granted their qualifications after one examination only, whereas in 1892 every board held at least three separate examinations, not to speak of subdivisions, so that we have in the year 1892, besides the 38·9 per cent. in the final, 47·1 per cent. in the second and 37·1 in the primary. Let us put it in another form. In 1892

[1] These remarks were made by Mr. Teale at the meeting of the General Medical Council on June 2nd in support of a resolution with regard to the present system of medical examinations, moved by himself and seconded by Dr. Pettigrew.

Digitized by Google

there were 9820 examinations and 4028 rejections, affecting at the outside about 2000 students, assuming that the whole number registering went through to the final examination. And so it comes about that every student, if he took his share of plucks, would be rejected twice in his career. And this calculation takes no account of the further subdivisions beyond those required by the Council, which entail a third pluck per man. There is a still further aspect of this question, the continuous rise in the percentage of rejections. Take each fifth year: 1861, 12·4; 1866, 14·5; 1871, 16 6; 1876, 22·2; 1881, 31·0; 1886, 34·8; and 1891, 39 3. "Quousque tandem?" It reads as if the more we multiply examinations the more fatal the final examinations become. Is the quality of medical training deteriorating or are the examinations becoming more fallible as tests?

This leads me to my second point: "The fallibility of examinations." There are three aspects in which many of our examinations seem to be faulty: (*a*) in the element of chance which is more or less inseparable from all examinations, even the best; (*b*) in the inevitable hurry with which a great many are conducted; and (*c*) in the unsuitable, misguiding questions which are frequently set.

a. On the element of chance I will not delay you long, merely quoting from a scientific exponent of statistics, Professor Edgeworth, who has discussed the point in a paper, the Element of Chance in Competitive Examinations.[2] As a result of a careful inquiry, partly statistical, partly from observation and comparison of actual facts, he says, speaking of the examinations for the Indian Civil Service, the Army, and Home Civil Service: "I find the element of chance in these public examinations to be such that only a fraction—from a third to two-thirds—of the successful candidates can be regarded as quite safe above the danger of coming out unsuccessful if a different set of equally competent examiners had happened to be appointed. A corresponding proportion of the successful—from two-thirds to one-third—must be described as unsafe. A rather larger number of the unsuccessful candidates would have a chance of succeeding at a re-examination." "This question may also be asked: What number of displacements is most likely to occur in the event of re-examination? The answer in some cases which I have scrutinised proves to be about one-seventh part of the successful." Again: "It may surprise even experts to hear that, as between two examiners, A. and B., who, upon the whole, are fairly well abreast, occasionally A. is ahead of B. and B. ahead of A. to the extent of 50 per cent." "It may be added that we have taken no account of what may be called extraneous elements of chance, such as the possibility of the candidate being out of sorts on the day of examination or of the questions being unfavourable to him."

As regards (*b*) the inevitable hurry, seeing how much we have undertaken in the way of examinations, it is more or less unavoidable—an "inseparable accident," as logicians would say. But it exists in varying degrees. It is less in the bodies who examine few candidates, more in the case of those who have to deal with large numbers, until it culminates in the—what shall I call it?—of the ten minutes' passing bell of the London Conjoint Examination, a patent device for making overwrought candidates nervous and for gaining it the unenviable reputation of not infrequently rejecting good men and passing inferior ones. One may fairly ask, "How can it be otherwise considering the amount of work which has to be got through?" And what a work. Let us look it in the face. In 1892 there were 9820 examinations of individuals. In each there would be on the average, I suppose, three subjects, which means 29,460. At least half of these subjects would involve a written, a practical, and an oral examination. So we must add two functions to one-half or one function to the whole, which doubles it, making 58,920 items in one year. How can this mass of work be done properly? What an array of examiners has to be employed. How can we guarantee that they are all fit for their work? There is no known means of testing their judgment, their appreciation of what ought to be required of a candidate, their appreciation of the fact that by the questions they set they in a great measure determine the future study of those who are coming forward. Are the questions set always unexceptionable from the point of view either of testing work or of setting the standard of future work?

This suggests the consideration of (*c*) unsuitable, misdirecting questions. Let me select a few from my museum of interesting specimens. We will begin by making a study of questions set to first-year's students, and as a preface to this let me quote a passage from Sir George Humphry's Report on Rejections (Minutes XIV., p. 68): "The burdening of the memory with mere facts which have no direct or obvious connexion with science or practice—with facts, that is, unassociated with ideas or practical utility—is, on the whole, of little value educationally or otherwise, and such facts make but a transient impression on the memory. Laboriously crammed together, with efforts worthy of a better purpose, they are with difficulty held until the examination crisis and then quickly escape with little regret at their departure. Indeed, the examination in each subject of professional study should be restricted to the general principles and the more important facts of the science, and should be of such a character as to induce students in their preparation for it to observe and think for themselves more than is now commonly the case. The examinations should be regarded from an educational point of view, with reference, that is, to the influence which they are likely to exert upon the character, the education, and the mental training of the students who are to come after, as well as with reference to their being a test of fitness for admission to the Medical Register." Perhaps the choicest examples of misdirected energy are to be culled from the questions set in "Materia Medica." And please remember that they are set for first-year's students, who are supposed never to have seen a sick human being except by accident, and under our present degenerating system, as I should call it, are discouraged from entering the wards of a hospital or the operating theatre during their first two years.

Questions.—"Name six of the most important emetics. What dose of each is necessary to induce vomiting, and how is it best administered?" "What is an enema? State the composition of each of the following," naming three, of which one is "enema magnesiæ sulphatis." This examiner seems to be enamoured of "enema magnesiæ sulphatis," as he asks the question again the year following. I wonder how many of those present here ever prescribed "enema magnesiæ sulphatis." "Contrast the physical and chemical properties of castor oil and oil of turpentine." "Name the pharmacopœial preparations into which potassii tartras acida enters and give their doses. Describe the action of this drug." "Give an account of sulphur, including its origin, physical properties, official preparations, and doses." "What is 'Lini farina'? Give its source and enumerate all the preparations into which it enters." Happy "linseed meal," it will hardly recognise itself when set on such a pedestal of honour. Let us take leave of Materia Medica for first-year's students with one quotation from a report of our inspector and a visitor: "The dosage of various drugs—including picrotoxine, phenazonum, apomorphine hydrochloras, &c.—many of which first-year's students probably never heard of. The majority of the questions could not be fairly included in the subject of Practical Pharmacy, as generally understood at the first examination of a student of medicine, although perfectly legitimate at the examination for the licence of a pharmaceutical society." And this is the kind of rubbish that the elaborate and costly machinery of a public examination has to waste its energies upon. I have a few morbid specimens from the Elementary Physiology Examination of the English Conjoint Board, but, thanks to the prevalence of good sense, this examination, as well as that in Elementary Anatomy, has disappeared.

From the questions set in physiology at the end of the second year I have selected three which seem to me to be open to criticism on principle as tending to cram. "Explain the terms myopia, hypermetropia, astigmatism. How would you correct these errors of refraction?" "Describe the appearances of the interior of the larynx as seen by the laryngoscope. What changes are noticed in phonation and respiration, and how are they brought about?" "What sounds can be heard on applying the ear to the chest? Explain exactly how they are caused." For my part I do not see how these questions can be answered except by means of mere verbal cram by those who cannot have worked clinically at "refraction," "laryngoscopy," and "auscultation." It is, however, when we come to the rather fancy subjects, such as hygiene and medical jurisprudence, that we meet, in the later stages of medical education, with the most questionable questions. In hygiene, for instance: "What do you understand by the expressions 'effective population,' 'dependent population,' 'density of population'?" "What impurities of a deleterious character are found in bread?"

Digitized by Google

"How ought a hospital to be constructed in order that each patient may have an efficient supply of pure air?" "Define the word 'nuisance' according to law. Show the different statutory provisions under which nuisances may be dealt with." "How will you dispose of the house-refuse (liquid and dry) of a large urban district?" Questions such as these are suitable enough in an examination for a diploma in Public Health, but are unpardonable when set for medical students. There is one more question to which I will take the liberty of suggesting the answer: "In the event of cases of typhoid fever occurring in a family what steps should be taken to ascertain that the water-supply and sanitary fittings are in proper order." My answer is—what I should do myself in such a case—"Send for the sanitary inspector."

Then as to Medical Jurisprudence, were an examiner to restrict his questions to those parts of the subject which are really useful in practice and with which in ordinary life a medical man is brought into contact, such as making a will, giving evidence in court, dealing with the insane, or with the apparently drowned, attempted suicide, and such like, he would be almost driven to give the same questions every year. As it is he goes forth into matters which probably never come before one practitioner in 10,000, and even then, no doubt, such practitioner would be obliged to refer to his book. For instance: "What are the effects produced on the living body by intense cold? What post-mortem appearances have been observed when death has resulted?" "Describe the symptoms and post-mortem appearances presented in a case of death from starvation."

With regard to the Final Examinations in the practical subjects of Medicine, Surgery, and Midwifery, it is an interesting fact that I find but few questions to criticise, but there are one or two comments I would venture to make as expressive of my own opinion. I will quote one question from a surgical and one from a midwifery and gynæcological paper: "Mention the complications which may be associated with chronic suppuration of the middle ear and describe the operation for opening the mastoid antrum." "Describe the operation for vaginal extirpation of the uterus." Now the setting of these questions for an ordinary diploma would seem to imply that they were operations that anyone might do without any more preparation than an ordinary student would get in reading for his pass examination, whereas they ought only to be attempted by men seriously intending to do the more advanced surgery. The "conclusion" of the three Visitors in 1882 on a similar point, in reference to operative surgery in an ordinary qualifying examination, seems to me to be a sound one. "That for every 'minimum' qualification the examination in operative surgery should be confined to emergency operations such as any practitioner may suddenly be called upon to perform—e.g., amputation, deligation of arteries, catheterism, urethrotomy, tracheotomy, &c., and should for the most part exclude complicated operations not of sudden urgency, such as ovariotomy, excisions of joints, plastic operations, lithotomy, lithotrity," (Vol. XIX., Visitation Report).

Let me conclude this part of my speech with another sentence from Professor Humphry: "Every question put must be regarded as a drop in the educational current of the future, and examiners must recognise that they are not simply judges of the students who come before them, but that they are in no less degree directors of, and so responsible for, the teaching of those who will follow" (Hunterian Oration).

My third point is, "Interference with clinical work and practical training." So far we have been dealing chiefly with facts and statistics. The next point does not admit of statistical proof and is one of testimony and inference. It is an opinion several times expressed to me by clinical teachers, and confirmed by young men who have recently completed their medical education, that advanced industrious students are unable to devote sufficient time to work in the wards and to self-training because they dare not tear themselves away from the drudgery of book-work, dreading failure in the examination. As a result of this deficiency in clinical training and the want of a larger element of self-education I frequently hear bitter complaints from medical men in country places who find their newly-fledged assistants woefully deficient in their fitness and adaptability to practice. They can talk about bacteriology and recondite neurology, but they have not the capacity for simple observation of the cases that come before them, or the power of turning to profitable use the knowledge they have acquired during their career as students. Testimony such as this may not be—is not—exact evidence; but as a contribution to the evidence, though a small one, I give it for what it is worth.

On this point let me quote a hospital surgeon, Mr. Tobin of Dublin. In his Introductory Address at the opening of the Session 1895-96 at St. Vincent's Hospital he says: "It thus appears that there are two stages in the curriculum—a preliminary scientific stage and a stage devoted directly to medical problems. It is with this second stage that I, as a hospital teacher, am most concerned, and the question that I ask you to consider with me to-day is this: Does the student spend his time during this stage to the best advantage? As far as I can see he does not, for, in place of being relegated to the hospital for his training during this second period, he is obliged to attend the school for theoretic lectures in medicine and surgery and for examinations in connexion with these lectures, and these examinations so dominate his views that he spends his time in hospital, not watching the changes in his patients, but on the look-out for ready-made answers to questions. If urged to make records of cases he does so reluctantly, for he knows that, from an examination point of view, it does not pay; and if, towards the conclusion of his course, he is offered the position as resident pupil in a large and busy hospital he often refuses it, because he is going in for his 'final,' and, of course, the one thing essential is to pass. His medical education, therefore, notwithstanding a large amount of hospital attendance, is literary rather than practical." "Moreover, education as at present conducted teaches us to see with the eyes of others rather than with our own. Further, the regulations are armed with a revolver in the shape of examinations, which enforces the obedience of students. Nothing else could keep alive such a system—one which, as it were by violence, keeps theory and practice apart."

Akin to this question of impairment of clinical study, and really a part of it, is the general outcome of our present system. Let me quote from the report of our visitor and inspector on the final examination of one of our leading universities, whose candidates have gone through a three years' course in arts before becoming medical students, and who, if any, ought to show satisfactory results of medical training. The report says: "In no case was the answering of any of the six candidates we heard examined brilliant—in the majority it was poor; but they had a sufficient knowledge of clinical medicine to warrant the examiners in passing them." In an examination of a conjoint board the visitor and inspector report: "Many of the candidates appeared to have a mere book-knowledge of these subjects; and when asked to explain their answers or to give some reasons for the statements they enunciated as if by rote were unable to do so."

Sir William Stokes, in opening the session at Meath Hospital in October, 1895, made the following statement as the result of his long experience as a teacher and as an examiner; "The student, wearied and weighed down by an accumulation of courses, and with the sword of Damocles in the shape of an annual examination ever hanging over his head, has neither time nor inclination to do anything that, in student parlance, will not 'pay' in the examination. It seems to me that the outcome of most modern changes in medical education is in the direction of making students read, not few books well, but many books badly, and that the brain has been looked upon too much as an organ with an unlimited capacity for retaining, digesting, and absorbing, in a given time, every ascertained fact, not only of medicine and surgery, but also of all the sciences auxiliary to medicine. The attempt to carry out the arrangement is fraught with real injury to many, with disaster to some. I can speak with some confidence on this subject after a long experience both here and in Oxford, and I have satisfied myself over and over again that the failure of a large proportion of candidates to answer up to the required standard was due, not to want of diligence and honest conscientious work on their part, but simply to brain exhaustion from attempting to overload it with facts which were believed to be essential."

Professor Mitchell Banks, a member of Council of the Royal College of Surgeons of England, for five years a most valued colleague on this Council, and an experienced teacher and examiner, said in an address to the Yorkshire College Medical Society in October, 1895: "When I began teaching in Liverpool the primary examination of the College of Surgeons consisted of little but anatomy, the physiology required being small in amount,

Digitized by Google

The students did a great deal of dissection and I was often surprised at the extent and accuracy of their anatomical knowledge; but for many years they have been steadily deteriorating in their knowledge, and I have been quite pained to note that when they came to be dressers in hospital their whole knowledge had vanished in a few months. It is the same as regards physiology. One department alone—that relating to the nervous system and to electrical experiments therein—is now more extensive than the entire subject was in my student days; but what is the result? Endless time is spent in galvanising frogs and making tracings on drums, whilst only the other day a physician complained that his clerks seemed to be ignorant of the simplest functions of the liver and kidney."

Dr. Haycraft, Professor of Physiology in University College, South Wales, in his introductory address in 1893, said: "In my opinion the medical student is overworked and badly worked. His examinations are in many cases foolishly detailed, entailing useless labour on his part, and any change that I should advocate would bring him less rather than more routine work." "Physiology has now become more than the rival of anatomy in the needless tax it lays upon the student's time."

We now reach the fourth point, "the five years' course." Let us consider how the five years' course will work out in practice. When in 1890 the Council added one year to the previous minimum of four years the aim of the Council, or at any rate the aim of many who were anxious to impose an additional year of study, was that this year should be a clear opportunity for clinical work at a hospital or for work partly clinical and partly as pupil to a registered practitioner, freed from the ordinary anxieties attending preparation for a bookwork examination. This fifth year so employed was to be the make-weight that was to compensate for what we have lost in the disappearance of the apprenticeship and of pupilage and the practical discouragement of clinical work during the earlier years of medical study. That it may be such a year is possible, but for most students it will have to be a sixth year, not a fifth. And why? As soon as the fifth year was added what did we do? We allowed a new subject—biology—to thrust itself into the first year, which would so occupy the time and energies of most students that they would have very little chance of passing in anatomy and physiology at the end of the second year. Hence the possibility of clearing off the medicine and surgery at the end of the fourth year being lost the fifth year must be frittered away on ordinary examinations and the clinical year becomes a sixth. The same result must happen to those who are plucked more than once—and the average student is plucked at least twice in his career, whether he be industrious or not. Some may maintain that such a result would be good, inasmuch as it would prolong their medical education and make them more fit for practice. I for one very much doubt it. Real education only begins when examinations have ceased, and I doubt whether, for the average student who is to become the family medical man, his chances of making a good practitioner do not grow worse instead of better by the prolongation of the time spent in school and hospital under pressure of examination.

The fifth and last point for consideration is "the cost to parents of multiplied rejections." This is an aspect of the question which I have never seen stated and one which doubtless in the opinion of many ought to be entirely ignored. It is worth being stated, nevertheless, and to some persons may be somewhat startling. Let us take the report on the Final Examinations in Medicine, Surgery, and Midwifery of the Conjoint Board for England of 1894. In medicine, out of 865 candidates, 365 were rejected—42 per cent.; in surgery, out of 916 candidates 388 were rejected—42 per cent.; in midwifery, out of 831 candidates 264 were rejected—32 per cent. Thus we have a total of rejections of 1017 out of 2612 examinations. Assuming that in every instance the candidate went up for re-examination, these re-examinations impose upon parents and others a cost of £4784 in one year in the final examination of one conjoint body representing two out of twenty licensing bodies. Nor is this all. Some of the rejected candidates have to take out fresh attendance tickets at their hospital, involving the expenditure of several guineas for an additional three or six months' clinical practice. And even this is not the limit of expenditure for those who come up from provincial schools. For these we must add return railway fare and the cost of living in London some five or six days. I know not how far I may have convinced the Council that under our responsibility medical education is drifting in a wrong direction, or whether I can persuade it, seeing clearly the evils that exist, boldly and with true statesmanship to face the question and find and apply the remedy. Surely our ponderous machinery, like the mountain in labour, is producing the "ridiculus mus." "Propter vitam vivendi perdimus causas." Losing sight of the end and aim of our educational machinery, we are worshipping the means and making them our golden calf. In what direction shall we look for release from this incubus? On what lines can we plan amendment? *We must decentralise.* We must unload our public examination. We must relegate to the schools not only to teach, but to examine and to certify in all secondary subjects, such as elementary biology, materia medica, pharmacy, hygiene, perhaps even chemistry, and certainly forensic medicine. Then let *all the rest* be covered by three public examinations—one in anatomy and physiology, presumably at the end of the second year of professional study; one in pathology and therapeutics at the end of the fourth year; and the clinical examination in medicine and surgery, together with the examination in midwifery (truly in midwifery, not in fancy gynæcology), at the end of the fifth year. Surely after that we may see the ten minutes' bell and all it implies abolished. The licensing bodies will be able to afford to examine more thoroughly, less hurriedly, to find out what a student really knows, and to re-examine those on the border line of pluck or pass. Then, when plucking examinations are reduced from nine[2] to three and become less matters of chance, there will be some room for calm clinical study, for self-training, for learning something during studentship of that very important and terribly neglected better half of the training of a true medical man, the knowledge and observation of a human being, that which was expressed in the wise saying of Andrew Clark, "I first attended to the man and then to the malady."

Could Brodie, or Green, or Lawrence, or Graves, or Stokes look down upon the work of this Council they would be amazed to witness how far we have departed from *their* ideals of the training of a medical man.

The Erasmus Wilson Lectures

ON

THE GENERAL PATHOLOGY OF BONE.

Delivered before the Royal College of Surgeons of England on March 16th, 18th, and 20th, 1896,

BY W. G. SPENCER, F.R.C.S. ENG.,

SURGEON TO THE OUT-PATIENTS AND THROAT DEPARTMENT, WESTMINSTER HOSPITAL; LECTURER ON PHYSIOLOGY AT THE WESTMINSTER HOSPITAL MEDICAL SCHOOL, ETC.

LECTURE II.[1]

Delivered on March 18th.

THE EFFECT OF ALTERATIONS IN THE CIRCULATION OF THE BLOOD THROUGH BONE (*continued*).

D. Venous congestion causes excessive bone formation.—Venous congestion is set up in bone apart from inflammation or as a result of chronic inflammation, the latter being of course by far the commonest cause. Simple venous congestion not due to chronic inflammation produces the clubbed fingers seen in cases of pulmonary and cardiac disease. A venous nævus in contact with bone may cause a raised patch. Indeed, it has been proposed to promote the formation of bone by artificially setting up venous congestion in a limb by means of elastic bands. This treatment has been used in tuberculous disease of the knee-joint. But it is through chronic inflammation that venous congestion is chiefly brought about—that is, by blood which stays a longer time in the capillaries than normal. There are two results of chronic inflammation which favour venous congestion. In the first place, the unstriped muscle on the wall

Digitized by Google

of the arterioles is replaced by inflammatory fibrous tissue, and therefore the constricting tonus of the vasomotor nerves can no longer act, and so the dilating influence of the blood pressure is unopposed. Again, as fibrous tissue forms around the vessels and gradually contracts it will press with greater effect upon the thin-walled veins than upon the thicker-walled arteries. Thus, as a result of chronic inflammation we have a tendency to dilatation on the part of the arterioles and to constriction of the smaller veins—venous congestion or a delay in the flow of the blood through the capillaries is the result. Venous congestion in soft parts, arising from chronic inflammation, is often seen to produce overgrowth in the leg, liver, lung, &c. The venous congestion such as causes overgrowth of the soft parts of the leg likewise extends its influence to the bone beneath and excites periosteal bone formation beneath the varicose ulcer. A syphilitic node forms in the same way. It is sometimes proper to cut through the periosteum to relieve pain, and the surgeon has then the opportunity of observing the venous congestion. But much greater formation of bone may be caused when a sequestrum, primarily due to an acute inflammation, remains for a long time and keeps up chronic inflammation. A bone containing a sequestrum may become of great size and the marrow cavity almost or quite obliterated. The enlarged bone contains an unusual amount of compact bone, which may approach to the density of ivory, whilst in it are spaces containing during life venous blood. The surgeon in operating upon such a bone can himself confirm the existence of venous congestion by the dark blood coming freely from the bone, and can compare this with the arterial blood from a bone acutely inflamed. In some the sequestrum is found enclosed in a cavity, in others only the cavity remains, the sequestrum having been absorbed. It is important to take note of any cavity, even although it be empty, when inquiring as to the origin of the cases known as osteitis deformans of a single bone. Being able to form some idea as to the origin of the condition in a single bone, we can pass on to the examination of cases in which more than one bone is affected, and so by an ascending scale of complexity reach the typical cases described by Sir James Paget. The conclusion we shall thus be led up to is that the typical cases are likewise the result of venous congestion.[2] A further complication still—viz., the connexion of osteitis deformans with new growth—will be afterwards dealt with. The production of new bone is, moreover, brought about by the chronic irritation of known chemical substances: nodes occur in chronic lead poisoning; the long-continued administration of phosphorus to animals promotes osteo-sclerosis and thickening of bone; turpentine and chloride of zinc have been successfully employed for the purpose of bone formation. Bony ankylosis of joints, especially where much new bone is formed, is largely due to the venous congestion brought about by chronic inflammation. A very marked as well as common instance is seen in the coral-like outgrowths about the joints of the phalanges in the horse. In man chronic septic conditions—"chronic pyæmia"—may cause ankylosis of many joints with large masses of new bone.

NERVE INFLUENCE ON BONE.

Trophic influence.—A direct control over the structure and nutrition of bone by the nervous system—in other words, a trophic influence—is not yet proved. Supposing, however, such a trophic influence to exist, alterations in structure and nutrition would follow a disturbance or loss of the connexion between the nervous system and the bone. This influence might originate within the nervous system and be connected with the bone by an efferent nerve or it might be a reflex action depending upon an afferent connexion as well as upon the centre and the efferent nerve. An efferent trophic influence is evidently cut off from muscle and atrophy of the bone follows when a motor nerve is divided. In infantile paralysis the degeneration of the muscles and atrophy of bone are the consequences of disease affecting cells in the spinal cord from which the motor nerves arise. In hemiplegia there is no special degeneration of the muscles, but only wasting from disuse. Now atrophy of the bones takes place under both the foregoing conditions, and, moreover, when a joint such as the knee becomes fixed in such a position that the muscles cannot act, wasting of muscles and atrophy of the bones likewise take place, although in this last case the nervous system and nerves are intact. Atrophy from disuse and consequently diminution in the blood-supply suffices, therefore, to explain the changes in bone without the need of supposing a loss of an efferent trophic influence. To the occurrence of afferent impulses which have, by reflex action through the central nervous system, a trophic influence on bone, Charcot and his followers have given support by ascribing to a loss of them the changes which take place in the bones of patients suffering from locomotor ataxia. Facial hemiatrophy with morphœa affects the skin of the face in the distribution of the fifth nerve and is accompanied by wasting of the bones of the face. It has been argued against the trophic view that locomotor ataxia is essentially a wasting disease, as the alternative name tabes dorsalis implies, that the changes in the shafts and ends of the bones do not differ essentially from those occurring in arthritis deformans or osteo-arthritis, and also that they closely resemble changes following on gout, lead poisoning, hæmophilia, leprosy, and senile decay. When a number of bones taken from ataxic patients are compared with those affected by osteo-arthritis the only distinction found has been a greater tendency to absorption and less tendency to new formation of bone in the ataxic patients. But, as is well known, whilst great absorption of the ends of the bone is perhaps the most frequent, large masses of new bone may be thrown out in some cases of tabes so as to completely ankylose the joint. The shafts of the long bones are likewise affected by absorption; indeed, so much may take place as to give rise to spontaneous fracture, and some have been called cases of mollities ossium. On the other hand, an increase of compact bone and a filling of the medullary canal have been met with, and after a spontaneous fracture in an ataxic patient much callus may be thrown out. Spontaneous fractures occur in epileptics, likewise in glioma (or syringomelia) of the spinal cord, in both cases following an atrophy of the bone. Therefore, if there be a nervous trophic influence, the afferent connexions of which are disturbed in ataxia and similar conditions, the result appears in an irregularity of bone formation, either a deficiency or an excess—in fact, a trophic ataxia. Other considerations support the view that there is a general regulation of the structure of bone by means of the central nervous system.

Transformation of bone.—From a study of the skeleton in various mammals it can be clearly seen that the architecture of each bone, and, indeed, of the elementary parts of each bone, has been made subservient to function. Each bone has been modelled, both as regards its form and its internal structure, in correspondence with the particular wants of the individual. If the femur of a man be compared with that of an anthropoid ape differences are found on account of man's erect position and peculiar movements of the femur in walking and running. When the adult femur is put alongside that of an infant it is seen that small changes have taken place during growth coördinating structure with developing functions (Mikulicz). The two functions which influence the structure and form of bone are the one statical—i.e., the line along which pressure is exercised—and the other mechanical, affecting the parts of the bone pulled on by muscle and ligament and the direction in which they pull. The internal structure of the upper end of the femur is well known, the arrangement of the septa and trabeculæ form arches and buttresses on a plan evidently directed towards sustaining the weight of the skeleton. The pull of muscles is not only occasional and intermittent, induced by the exercise of the will, but there is also a constant involuntary tension kept up upon the bones by the normal tonus of muscle, each muscle being taut between its two points of attachment. Ligaments are likewise tense (Von Recklinghausen, Wolff). If the bones be active agents, the lines of transmission of force and the direction of the pull of muscles must be attended by special tissue changes in the parts of the bone involved. And such changes postulate a sufficient blood-supply. Conversely, the part of an adult bone which receives the most blood possesses the wherewithal for change not only under normal conditions, but also when abnormal ones supervene. Hence the liability of an adult bone to more frequent pathological changes in one part rather than another may often be explained by reference to its statical or mechanical functions. When the statical conditions under which a bone acts become altered its whole internal structure may undergo a transformation. When after a fracture union in a more or less oblique position has followed, then the axis

[2] A typical case of Osteitis Deformans under the care of my colleague Dr. de Havilland Hall in the Westminster Hospital was recently shown at the Medical Society. The superficial venous congestion over the enlarged bones was very well marked.

Digitized by Google

of such a bone as the femur becomes altered, so that the lines by which force is transmitted, the way in which each one of the septa has to bear its share of the weight of the body transmitted through it, is changed. After an oblique union of the femur the septa are found to have a different direction from that existing in a normal bone. They accord with the new direction which the lines of force supporting the weight of body now take in consequence of the oblique union. Following therefore on a fracture there are two processes which go on in a bone, the formation of callus at the site of the fracture and the transformation in the direction of the septa, and this in both the distal and proximal fragment. Indeed, arches for strengthening union may stretch across the callus so as to unite the septa of one fragment to those of the other. Whilst the callus is inflammatory in origin and shows no sign of being under any nervous influence, the transformation of structure following on the altered axis of the limb must be determined by a controlling nervous influence, which coördinates and adapts the changes to special ends. A fracture is not necessary in order that this transformation may occur, the same result follows the bending of the bone from rickets. If a rickety bone be split down the middle the filling of the marrow cavity at the bend, the buttresses formed in the concavity of the curve, and the direction of the septa will be found to accord with the altered statical conditions brought about by the curvature. So, also, in the bones of the arm there occurs a transformation of the internal structure in consequence of oblique union or of rickety curvature in accordance with the change in the direction in which the muscles pull. A more striking instance still, because it involves a coördinating influence extending over many bones, occurs as a consequence of spinal curvature. In specimens of lateral curvature we find a thick buttress of compact bone on the side of the bodies of the vertebræ in the concavity of the curvature. This new bone is similar in character with that forming in the bent bones of the lower limbs, many bones being involved instead of one. In cases of angular curvature the thickening is on the anterior aspect. In kyphosis a marked formation of bone takes place at the site of the anterior common and articular ligaments, as well as ossification of the ligaments between the laminæ and between the spinous processes. These are all instances of a coördinate strengthening of a spine weakened by curvature—an adaptation of structure to altered functions. Besides the foregoing evidence concerning nervous regulation of the structure of bone, the skull, the orbit, and the lower jaw may be considered as bones which have been modelled for the brain, eyes, and teeth, which they respectively shelter. Following the shrinkage of the brain on the removal of an eye or tooth we may have changes in the bone which appear likewise to afford instances of the regulatory influence of the nervous system.

CHANGES IN BONE DUE TO AN IMPAIRMENT OF GENERAL NUTRITION.

The mineral salts of bone.—Analyses of the amount of the mineral salts of bone present some discrepancies owing to difficulties (1) in getting rid of all water without destroying the animal substance, and (2) on account of the varying amount of marrow. If dentine were to be taken as the type of dry, fat-free bone, the amount of mineral matters would be found to approach 75 per cent., whereas the usual statement is that the mineral salts form two-thirds of the bone by weight. They are chiefly composed of lime and phosphates. The amount of lime in bone increases up to puberty, as the following figures show.

In a fœtus of from six to seven months there were 59·5 per cent. of the fat-free ash; in a child two years old 65·3 per cent.; and in a child five years old 67·8 per cent. (Voit).

A young pigeon's femur contained 53 per cent. of lime, and an old pigeon's femur had 58·9 per cent. of lime in the fat-free ash.

A rabbit at birth had 53 per cent. of lime in the fat-free ash, one at one month had 58·9 per cent., one at three months had 67·7 per cent., and one full-grown had 74 per cent.

During the growing period of life there is at least, therefore, a small intake of lime for the bones. After puberty it is otherwise. Nelaton and Sappey compared the composition of the same lumbar vertebra at each period of life. They found but little variation throughout except a slight increase of organic material in old age due to senile atrophy.

Modes of taking in lime.—Lime may possibly be taken in as a hydrate, carbonate, and phosphate. Since part of the phosphoric acid can be formed in the body from the phosphorus in the albumin of animals or plants taken in as food lime will be required to combine with it. Milk is the great source of both lime and phosphates for young animals, the mother usually suckling her young until more than half of the bone has formed. A litre of cow's milk contains 1·7 grammes of lime, whereas a saturated solution of lime water has only 1·3 grammes per litre (Bunge). Milk has, therefore, the advantage of lime water even as regards lime, to say nothing of its other constituents. The ash of milk is practically identical with the ash obtained by the combustion of a suckling animal, as is to be seen in the following table.

—	Ash of dog's milk.	Ash of suckling rabbit.	Ash of puppy.	Ash of kitten.
	Per cent.	Per cent.	Per cent.	Per cent.
Lime	34·4	35·0	35·8	34·1
Phosphoric acid	39·5	41·9	39·8	40·2

No other food is such a source of lime as milk. Leguminous plants contain only one-tenth, the yolk of egg one-fifth, and bread and meat one-twentieth of the amount of lime contained in milk. But there is some evidence to show that the lime and phosphates may be absorbed in their ordinary inorganic state. If young rabbits be fed solely on oats, which are very deficient in lime, rickets is produced. When, however, chalk is added to the oats the rabbits thrive and remain free from rickets (Weiske). Experiments of this kind have been held to show that rickets may be produced by deficiency in the supply of lime salts and that an absorption of chalk can take place from the intestines. Such absorption certainly takes place in birds, who habitually seek calcareous material to form the shells of their eggs, and who lay soft eggs when deprived of lime. It is, moreover, said that young pigs confined in a stye and fed on meal, or young cattle fed solely on hay or dry pasture, may be kept from rickets or fragility of bone by the mixture of chalk or slaked lime with their food. Perhaps, also, lime can be absorbed from spring water. Calcium is the essential base. It cannot be replaced by barium, strontium, or by magnesium.

The excretion of lime and phosphate.—By far the greater part leaves by the fæces and only a comparatively small amount by the urine—it is said only 0·25 gramme of lime per diem. Of course, the absolute amount of mineral salts in the fæces will largely depend upon the amount in the food. But it can be also proved that the intestines actually excrete lime and phosphoric acid, for these substances are found in the fæces of a starving animal. A recognition of these facts makes clear that conclusions drawn from the analysis of the urine as to the escape of lime and phosphoric acid are entirely untrustworthy, not only because the major part of the mineral matter of the food always leaves by the fæces, but on account of the excretory power of the intestines. That an excess of salts should appear in the urine during the earlier stages of a rapidly progressing mollities ossium is very likely, although the same need not be the case during the later stages of the disease. But the formation of concretions in the urinary tract is no evidence of excessive excretion, but merely of precipitation owing to the alkalinity of the urine. The urine naturally tends to become alkaline when an osteomalacic patient has to take to her bed and when the deformity of the pelvis makes micturition difficult. It is impossible, therefore, to form any conclusions concerning the escape of the lime salts until the difficult analyses of the fæces shall have been more largely resorted to.

Imperfect ossification and rickets.—There seems no sufficient ground for supposing an absolute want of lime salts in the diet of a child. Any diet, however inadequate from other points of view, would contain enough of these salts. The mineral salts may not be absorbed; it has been thought that intestinal catarrh may prevent absorption. Intestinal catarrh, however, is no necessary accompaniment of rickets, and even when it exists we have no proof that an absorption of mineral salts is prevented. On the other hand, we have proof that it prevents the absorption of fat, which may be found in the fæces when there is intestinal disturbance.

Indeed, there is more evidence to show that rickets occurs from want of fat than from want of mineral salts. Rickety children are generally found to have had too little fat in their food, whilst, conversely, children fed on plenty of milk, bacon, &c., remain free. Moreover, the administration of fat in the form of cod-liver oil is a most satisfactory kind of treatment. Fat, added to lean horseflesh, has prevented rickets in young carnivora, and oilcake given to ewes on a poor farm may stop the otherwise inevitable production of rickety lambs. Rickets is thus seen to be essentially due to an impairment of general nutrition, cold, damp, and deficient ventilation sharing also in the causation of the disease as instanced in the case of puppies kept in damp cellars. But, further, it is important that the animal should be fed on its proper food, and therefore an *a priori* objection may be raised to many of the experiments made on animals. The very fact of giving an abnormal diet or of withdrawing some customary article may itself disturb the general nutrition and lead to rickets. Monkeys and other tropical animals kept under artificial conditions in this country show a tendency to rickets, a disease from which they do not suffer in their wild state. Indeed, anything which impairs general nutrition, such as the delicacy of constitution produced by interbreeding, especially in dogs, tends to originate rickets. Hence also it frequently complicates the wasting diseases of children, such as syphilis. The rarity of rickets among the poor in climates warmer than our own may be due not only to the cheapness and plenty of vegetable foods, such as maize, which contains fat, as well as the more general use of milk amongst the poor, but also that not so much of the fat is required for consumption in order to maintain the heat of the body. An impairment of general nutrition, rather than the absence of any special articles from the diet, serves therefore as the best explanation of rickets. The bone-forming cells being at the time particularly active are amongst the first to suffer. In order to form bone these cells have to extract from the blood the phosphate and lime they require just as do other secretory cells—e.g., those of the mammary gland. The ash of dog's blood contains only 0·9 per cent. of lime and 13·3 per cent. of phosphates, and the ash of dog's serum 2·1 per cent. of lime and 5·9 per cent. of phosphates. Ossification clearly demands some energetic action on the part of the cell in gathering out from the blood and secreting these salts which exist in such small quantities in it. A supply of phosphorus in some form must be constantly necessary for that element is an essential characteristic of nucleo-albumin, and it is upon its nucleus that the activity of a cell depends. The causes of the various forms of late rickets are similar in principle to those giving rise to the earlier variety, such as want of food, a lack of fat in the diet, cold, damp, bad air, and exhausting diseases. Girls suffer the most, perhaps owing to menstruation and anæmia. One girl was dying from phthisis and another from exophthalmic goitre when the bones were attacked. Special cases in boys about puberty have been attributed to bad habits (Lucas). But there are two other phenomena met with in some cases of rickets which are not due to delayed ossification. There may be rapid absorption of bone or, on the other hand, an excessive bone formation.

Bone absorption in rickets.—Rapid absorption of bone in consequence of an increased supply of arterial blood happens in severe cases of rickets. There may be external signs of inflammation—viz., redness, heat, pain, and excessive sweating—and this not only in the neighbourhood of the epiphyses, but also in such flat bones as the skull. The ends of the long bones become of a much more cancellous structure, whilst the skull may be rendered as thin as paper, or at least much more porous than normal. The older the patient the more striking is the fact. After a child has long learnt to walk it may be attacked by rickets, and bending may still occur. But as the cases become older and approach puberty multiple fractures happen instead or take place along with the curving.

Bone formation in rickets.—On the other hand, in the later stages of rickets or where the disease progresses but slowly an excessive formation of bone takes place. This may be seen as a great thickening of the skull and as osteo-sclerosis in the long bones. I have already brought forward the fact that excessive formation of bone is due to venous congestion, whether arising from chronic inflammation or not. This excessive formation of bone takes place both in men and animals. The shafts of the long bones undergo marked osteo-sclerosis—they become heavy and very hard. The skull may be thickened by porous bone (Briscoe), but even still more marked thickenings of the skull are seen in animals. In monkeys and lions dying in the Zoological Gardens Sutton has described such extreme thickenings of the skull as to cause death by pressure on the central nervous system. It will be noted that these tropical animals are liable in this country to both early and late rickets, although they remain free in their wild state. I have already noted a parallel instance in man—viz., the absence of rickets from India as compared with this country.

Senile changes.—In all the changes of bone taking place in the decline of life we must recognise as one of the factors the gradual failure of general nutrition. It may be an important factor in some cases, in others only one among others. With diminished muscular use will come a diminished vascular supply, and so a smaller formation of bone in the parts of the bone pulled on by muscles. This may be combined with small disturbances of the regulating control of the nervous system without any nervous disease.

ACTINOMYCOSIS INVOLVING THE SKIN, AND ITS TREATMENT BY IODIDE OF POTASSIUM.

[WITH COLOURED ILLUSTRATION.]

BY MALCOLM MORRIS, F.R.C.S. EDIN.,
SURGEON TO THE SKIN DEPARTMENT, ST. MARY'S HOSPITAL.

ALTHOUGH actinomycosis in the human subject is probably not so rare as till lately it has been supposed to be, it is still met with, or at any rate recognised, infrequently enough to make it worth while to report cases in which there has been an opportunity of studying its evolution and clinical manifestations and the effect of treatment. The following case which I have recently had under observation appears to me to be important as an illustration of the therapeutic action of iodide of potassium in this disease, more especially as the efficacy of this remedy in actinomycosis seems as yet to be imperfectly appreciated in this country. For the notes of the case I am indebted to my clinical assistant, Mr. J. W. Skevington.

A single woman aged fifty-nine years came under my care at St. Mary's Hospital on Nov. 18th, 1895, with a large swelling over the lower jaw on the left side. About Oct. 10th she first noticed a small nodule behind the ramus; it was just underneath the skin, and in about seven days began to discharge. It was very painful and continued to increase until she came to the hospital. The patient had for the greater part of her life been in service as a housemaid, but for about a year before the beginning of her illness she had made her living as a needlewoman. She stated that she had never lived over a stable, and had nothing to do with horses, cows, or other animals, nor with grain, hay, or straw. There was no history of a blow or other injury and she could throw no light on the origin of the disease. Her record of previous illnesses showed nothing that could be interpreted as having any bearing on her condition, nor was there anything of significance in her family history. She had a large dark red nodular tumour with a sharply circumscribed edge on the left side of the face. It extended from the angle of the lower jaw forwards to the corner of the mouth, upwards to the zygomatic arch, and downwards over the sterno-mastoid for about two inches. Here and there on the surface there were small scars, and the skin, especially at the lower part in the neck and about the corner of the mouth, was drawn into folds by cicatricial contraction, giving the swelling a puckered appearance about the edges. On the most prominent part, in the temporo-maxillary region, the surface of the mass was irregularly raised into nodules varying in size from a split pea to a small bean, each having a small opening at the top, the position of which was marked by a yellow bead of pus. On squeezing the nodules a little sero-purulent matter escaped. In this discharge were found firm yellowish-grey granules which microscopic examination showed to be masses of actinomyces or ray fungus. The skin over the whole mass was brawny and reddened. To the touch the swelling at first gave the impression of cartilaginous hardness, but on firm pressure between the fingers it was felt to be elastic. There was no

Digitized by Google

fluctuation. Narrow spurs of infiltration also extended upwards behind the lobe of the ear and backwards to the posterior border of the sterno-mastoid. A hard lump of the size of a large hazel nut could be felt under the buccal mucous membrane. The structures forming the cheek were infiltrated and firmly fixed to the jaw, especially towards the angle, but the bone itself was not implicated. There were no teeth in either jaw except the left superior external incisor and canine. No enlargement of glands, either concatenate or supra-clavicular, could be felt on the left side of the neck, and there was no evidence of secondary growths. There was no trismus, but the patient complained of great pain, particularly on mastication, and the nodules were tender on pressure. She had a poor appetite and slept badly, but otherwise there was no disorder of the general health. How the infection was conveyed in this case there is no evidence to show, but of the nature of the disease there was no doubt. The microscopic examination was conclusive; apart from this, however, the situation and appearances of the swelling (see coloured plate) were characteristic. The internal administration of iodide of potassium was begun on Nov. 21st, when the following mixture was ordered to be taken three times a day: Potassii iodidi 15 gr., spiritus ammoniæ aromatici 20 minims, decoct. cinchonæ ad ℥i. For the first three days after the commencement of treatment the pain was worse and the discharge was profuse, but after that the good effect was soon manifest. The pain abated, the swelling became paler and softer and began to shrink. After ten days of the treatment only slight traces of the fungus could be discovered in the discharge, which was very scanty. The patient was exhibited to the Dermatological Society of London on Dec. 11th, and at that time the growth had diminished to half its former size, and was much softer in consistence while the pain was very slight. On the 16th the dose of iodide of potassium was increased to 20 gr. and on Jan. 27th, 1896, to 30 gr. three times a day. The improvement continued, and, in short, the history of the case from the time the patient was brought under the influence of the iodide was a record of uninterrupted progress towards cure. Together with the retrocession of the local process appetite and sleep returned and the woman felt better than she had done for a considerable time. At the beginning of February the swelling had nearly disappeared, the sinuses had healed up, and only a trace of the disease was left. When last seen (May 28th) the patient was well, but was still taking the iodide.

There can be no doubt that actinomycosis has often been mistaken for gumma or other manifestation of syphilis, and the erroneous diagnosis must have appeared to receive confirmation from the beneficial effects of iodide of potassium. In other cases the disease has been looked upon as tuberculous or has been taken to be a malignant growth—generally sarcoma, to which, indeed, it sometimes bears a close resemblance. It is generally easy enough to recognise actinomycosis when one is alive to the possibility of meeting with it in a given case; but the appearances are certainly very puzzling when such a contingency does not happen to be present to the mind. As actinomycosis, even when liberal allowance is made for errors in diagnosis, is not a common disease, and as there must be many members of the profession in this country who have never seen a case, it may not be amiss to give a short account of it in its ordinary manifestations. I have no pretension to be able to add anything to what is already known about the disease, but I have lately had occasion to look through the recent literature bearing on the subject, and as even the most modern English text-books and special treatises give only a few lines to the description of the disease so far as it attacks the skin, I may, perhaps, be excused for trying in some measure to fill the gap at least provisionally.

Actinomycosis is a parasitic disease, the lesions being the result of a reactive process caused by the presence in the tissues of a living irritant, the actinomyces or ray fungus. This was first described as it occurs in the so-called osteo-sarcoma of animals by Rivolta in 1868 and more fully and more accurately by Harz and Bollinger[1] in 1877. It was Harz who gave the disease caused by the parasite the name of "actinomycosis." In man it was first definitely recognised by J. Israel.[2] The parasite had been seen and drawn by von Langenbeck[3] in 1845, but its nature was not understood by that great surgeon. Three cases were described in 1853 by Robin and Laboulbène[4] which appear to have been instances of actinomycosis, and four years later the characteristic granules were noticed in pus from an abscess of the chest wall by Lebert,[5] who, however, was unable to give an opinion as to their nature. The parasite had also been drawn independently by Mr. T. Smith[6] when examining the tissues of an obscure case for Sir James Paget about 1855. In 1879 Ponfick proved that the disease as it occurs in man is pathologically identical with that met with in animals.

Actinomycosis may attack almost any part of the body; but there are three principal points of invasion, the neck, the chest, and the abdomen. The cervico-facial region is the most frequent site of the disease; it has been estimated that some 55 per cent. of all cases have this localisation, but the proportion is probably higher than this; thus of thirty-eight cases published in France up to the latter part of 1895 the disease was in this region in thirty-five. The lung and abdominal viscera come next. The limbs suffer comparatively seldom. Cases are, however, recorded in which the disease attacked the hand by Bertha[7] and Müller[8] and the lower limbs by Marten,[9] and Pringle.[10] Crookshank and Kanthack[11] maintain that one variety of the affection of the foot familiar to Indian practitioners under the name of "madura foot" or mycetoma is in reality a form of actinomycosis caused by a variety of the ray fungus, but this theory must be considered as yet "not proven." The points of difference between the fungus of actinomycosis and that of mycetoma have been fully described by Surveyor and Boyce.[12] The skin is extremely seldom primarily attacked by actinomycosis, but it is very often secondarily invaded by extension of the process from the underlying tissues.

In this paper I am chiefly concerned with actinomycosis as it affects the skin, and in the following description I will take the temporo-maxillary form of the affection as the type. The most common situation of the disease is the space roughly limited behind by the ramus of the jaw, below by the body of that bone, and above by a line from the temporo-maxillary joint along the zygoma. This localisation is doubtless due to the fact that the fungus as a rule finds its way into the tissues through the mouth, the point of entrance being a carious tooth or an erosion of the mucous membrane. Bertha[13] reports two cases of direct inoculation of the skin of the hand by means of grain. Sometimes it gains access through a breach of the skin surface caused by injury; what appears to be an instance of this mode of invasion has lately been reported by Guillemot.[14] A man was struck on the face by a piece of wood and a few weeks later an actinomycotic swelling developed on the exact site of the blow. Müller[15] has recorded a case in which a woman ran a splinter of wood into her finger and two years later a swelling formed in the same situation which was proved by microscopic examination to be of actinomycotic nature; the chip of wood was found imbedded in the diseased tissues. Although there are no precise data by which to estimate the period of latency I find it difficult to believe that it can be as long as two years; it appears more probable that inoculation took place through the wound. In animals the fungus is mostly conveyed into the body by the food, and in man the fungus is no doubt sometimes introduced by tiny pieces of grass, hay, corn, &c., which are chewed or unwittingly swallowed. The most common habitat of the fungus is the surface of certain vegetable substances, especially grass and cereals, particularly in the dry state. A piece of straw may be at once the means of conveying the fungus into the mouth and the instrument of inoculating it in the tissues by making a tiny scratch on the mucous membrane. Thus Poncet[16] reports a case in a woman who was accustomed to carry in her mouth wisps of straw for

tying up vines; and another[17] in a man who had a habit of chewing bits of grass and straw; Dubreuilh and Frèche[18] report a case in a man who used to pick his teeth with straw, with which he sometimes made his gums bleed; Monestié[19] relates one in a girl who was in the habit of chewing straw; and Besse[20] one in a man who was accustomed to chew grain. Guermonprez and Augier[21] have recorded a case in which a man wounded his gum with a piece of cornstalk; eight days later a hard, painless swelling, which proved to be of actinomycotic nature, appeared in the exact situation of the scratch. There is some evidence that the actinomyces may be introduced into the system in meat from animals that have suffered from the disease, in vegetable substances such as cereals, potatoes, &c., and even in milk.[22] The disease may also be transmitted directly from animals to human beings or from the latter to each other. Baracz[23] has placed on record a case in which it was communicated by a man to a woman by kissing, and cases in which it has been transmitted from animals to human beings have been reported by Poncet, Mayde, Bulhoes-Hartman, and others.[24]

As regards the etiology there is little more to be said; neither age nor sex can be regarded as a factor except in as far as they have any connexion with occupations exposing to the risk of infection. That the soil has an influence, favourable or unfavourable, on the growth of the parasite in the tissues is obvious, not only from the very different degrees of severity of the disease, but from the very marked differences of type in which we meet with it clinically. Of the causes of these differences, however, we know nothing. The published literature might suggest that the disease is far more frequent in some parts of Germany and particularly in Austria than elsewhere, but this is probably in large measure due to its being more carefully looked for in those countries. It is significant that whereas France used to be thought to be exempt from actinomycosis, no fewer than twenty-four cases have been recorded in that country since 1894; it is still more significant that of that number twelve have occurred in Lyons, nine of them in the practice of one surgeon, M. Poncet.[25] It appears a fair inference, therefore, that actinomycosis will be recognised more frequently the more carefully it is looked for. In many cases, as in the one reported above, the mode of infection cannot be precisely determined. According to M. Arloing,[26] the spores are scattered about in nature in considerable abundance, being generally present in greater or less numbers on organic substances in course of becoming mouldy. These spores may penetrate by inoculation into the tissues and they may also gain entrance through the respiratory passages, spreading thence into various parts of the organism by the bloodvessels. As the mycelial tubes have no distinct sheath such as is found in ordinary moulds, they are easily broken up and may be scattered about to great distances. I give these facts on the authority of M. Arloing, a man not given to uttering base scientific coin; the wonder, therefore, is not that actinomycosis should often develop without traceable cause, but that it is not a much more common disease than it is.

The fungus having found its way into the economy after a period of incubation not less than four weeks sets up an inflammatory process, the exact course and results of which are dependent on the nature of the tissues in which it is embedded. The essence of the process is that a development of granulation tissue takes place round the fungus; a nodule is thus formed, the interior of which soon breaks down into a thin liquid containing tiny granular bodies. By-and-bye the neighbouring nodules coalesce into a tumour-like mass, hard and solid at first, but before long suppurating in different places and giving rise to small abscesses, which may run together and form cavities of considerable size. The skin covering the swelling is at first red and brawny; as tension increases it becomes livid and soft and finally gives way, generally in several places. Through the openings there escapes a thin serous or sero-purulent discharge, containing yellowish grey or whitish granules, which to the finger feel firm and resistant; these are masses of spores of the ray fungus. The openings of the sinuses closely resemble those leading to diseased bone, but on probing no bare bone is struck. The sinuses have soft, fungating walls and are often partly filled with broken-down tissue; they communicate with cavities lined with similar material in which the characteristic yellowish granules are present in greater or less abundance. For a considerable time the process is confined to the soft tissues, especially to the subcutaneous cellular tissue, muscles, &c. The periosteum may also be thickened, but the bones are very seldom attacked, and then only secondarily. In some rare cases, however, the process invades the bones almost from the first; thus Poncet[27] has recorded a case in which the bones of the upper jaw and the corresponding half of the hard palate were completely destroyed in five months, the soft parts of the cheek remaining unaffected. It is a curious fact, of which I have seen no explanation, that in animals the bone is always invaded, and, in fact, is generally the starting-point of the process, whereas in man the general exemption of the bone is one of the characteristic features of the disease. On the other hand, suppuration, which is the rule in the human subject, never occurs in animals. The suppuration caused by the actinomyces itself in man is of a peculiar character, the pus formation being extremely scanty and the pus itself generally thin, though very sticky. As the process continues, however, pus-cocci gain access and set up active suppuration, the ravages of which extend wide and deep, destroying the temporal, masseter, and pterygoid muscles and not sparing the bone. In this stage the characteristic features of the disease are lost in a mass of inflamed and disintegrating tissues, fungating here and there through the skin, which is riddled with sinuses and fistulæ intercommunicating with each other in an inextricable labyrinth.

The appearances of actinomycosis as it affects the skin in other parts of the body have been well described by Pringle[28] in the case of a boy under his care in the Middlesex Hospital in whom the primary seat of disease appears to have been the respiratory tract. The skin lesions were situated on the back. "The most striking feature of the eruption is constituted by enormous livid, fleshy, sarcomatous-looking outgrowths of mottled purplish and yellow colour. ..... All the growths feel pulpy and fluctuating and are not tender; each growth presents at least one, usually several, small crateriform ulcerative openings, from which a clear, rather sticky fluid constantly exudes. ..... In each of these ulcerative surfaces there is an accumulation of purulent fluid of pale sulphur-yellow colour, which is seen to contain innumerable tiny granular specks." Over the part of the chest there were deep brown pigmented sunken cicatrices, the marks of lesions similar to those on the back, which have discharged their contents. Over the great trochanter are three similar pigmented scars, which still show some signs of activity.

Actinomycosis may run an acute course, but as a rule the process is chronic, sometimes with occasional exacerbations. The typical form, that which affects the parts about the angle of the jaw and the temporal region, often begins with pains about the back molar teeth, which may be decayed, or in the temporo-maxillary joint itself, where the pain is sometimes so intense as to suggest arthritis. Another symptom which not infrequently precedes the appearance of swelling is trismus, the closure of the mouth apparently being due to reflex spasm of the masseter and temporal muscles caused by the irritation of the parasite. The trismus is often so severe as to make feeding a matter of great difficulty. The swelling usually first shows itself at the angle of the jaw and spreads upwards along the ramus, infiltrating the temporal region and the cheek and sometimes the part behind the ear. From the slight degree of redness of the skin covering it and from its indefinite outline and nodular surface the swelling is in its appearance at first more suggestive of a new growth than of an abscess. To the finger it feels solid like cartilage or even wood, but yet elastic. As Poncet says, an actinomycotic swelling gives to the touch a sense of something unfamiliar, its consistence being between that of a hard tumour and of inflammatory œdema; the impression given to the finger is, as he expresses it, as if the connective tissue in the affected region had been infiltrated with some coagulating substance. Diffused through the mass of the swelling nodules of varying

size can be felt. On passing the finger into the mouth the swelling can be felt projecting into the cavity; the mucous membrane is sound and the mass can be felt lying outside it, smooth and dense as on the face. Pointing as a rule takes place towards the exterior, not towards the mouth. Waring[29] has, however, recorded a case in which the swelling burst into the buccal cavity. After a variable time slight fluctuation may be perceptible at one or more places, and the skin in those spots becomes livid and thin and finally breaks, giving issue to a little fluid in which are seen the granular masses containing the parasites. Squeezing causes the escape of more yellowish bodies, but not, as a rule, of any amount of pus. Long sinuses are formed from which matter containing the yellowish granules of the fungus is discharged from time to time. When the contents have been completely got rid of the opening heals up, and when there are several such small "extinct volcanoes," if I may call them so, the contraction gives rise to the puckering in the swelling which is one of the most characteristic appearances of the disease. There is seldom any enlargement of neighbouring glands, the fungus being too large to make its way along the lymphatics. When, however, suppuration runs riot and the original disease has become complicated by the invasion of pyogenic microbes the glands may be involved in the general conflagration. Secondary foci of the disease may develop in neighbouring parts, as the neck, the cheek, the temple, &c., the fungus burrowing its way along in the loose connective tissue, under fasciæ and in the sheaths of blood-vessels and muscles. The evolution of these secondary swellings is similar to that of the original mass.

In the ordinary chronic form actinomycosis in the earliest stages, when the lesions are purely local, is not accompanied by any particular derangement of the health, though much suffering may be caused by pain and the patient is weakened by want of sleep and inability to take food; if the process continues his strength is further drained by prolonged suppuration; and if the larynx, œsophagus, lungs, nervous system, &c., be attacked corresponding symptoms will be produced. The disease if left to itself tends to spread both by continuous extension and by metastasis. It may extend downwards in the subcutaneous tissue in the front of the neck or at the side along the sterno-mastoid, reaching the supra-clavicular region or passing into the axilla, and fixing the whole neck from the chin to the sternum in a rigid casing;[30] or passing below the superficial cervical fascia it may spread downwards into the anterior mediastinum, perhaps ulcerating into the air passages on its way, and finally attacking the lungs and the heart; sometimes it extends upwards to the base of the skull, attacking the meninges and the brain, or it invades the spinal cord. In any of these lines of extension the mass may erode the walls of blood-vessels with consequent formation of fresh foci in the viscera. Death may occur from exhaustion, amyloid degeneration of the liver, &c., or septicæmia. In certain rare cases actinomycosis runs an acute course, beginning suddenly with high fever and great swelling of the neck, sometimes spreading to the floor of the mouth, the tongue, and the pharynx; the affection in such cases strikingly resembles angina Ludovici and death may occur in less than a week from the onset.

Fortunately, actinomycosis is fairly amenable to treatment if taken in time, and if properly dealt with the formidable complications that have been alluded to can often be prevented. It must be borne in mind, however, that actinomycosis, particularly in the temporo-maxillary form, is of two very distinct types—one comparatively mild, in which the affection is easily controlled or may come to a standstill or undergo spontaneous cure, and another in which it has in it an element of malignancy which simply defies treatment. There can seldom nowadays be any difficulty about the diagnosis, except in the initial stage, before the skin has given way and allowed the characteristic granular bodies to escape. The yellowish-grey bodies can readily be identified with the naked eye when once they have been seen, but reliance must not be placed on such perfunctory inspection; masses of cholesterin crystals have been taken for actinomyces, and a microscopic examination should be made in all cases. Even with the aid of the microscope the characteristic bodies are not always easy to discover. Microscopically the granular bodies consist of rounded masses of leptothrix filaments surrounded by a fringe of club-shaped bodies radiating from the centre. The morphology and life-history of the parasite will be found fully described in the writings of Ponfick,[31] Israel,[32] Crookshank,[33] and Kanthack,[34] to which I refer the reader. Poncet, who has given great attention to the subject, holds that the diagnosis can generally be made from the symptoms alone. The signs on which he lays stress are: (1) the character of the pain, which is not continuous, is mostly worse at night than in the day, is not tensive like that of an abscess, and is often not relieved by incision; (2) the early occurrence of trismus not dependent either on pain—since it is present in cases where there is little or no pain—or on swelling; this symptom according to Poncet is pathognomonic; (3) the situation and peculiar wooden feeling of the swelling; and (4) the respect for the bony structures generally shown by the process. The absence of glandular enlargement is another distinctive feature. Actinomycosis might possibly at the very outset be mistaken for periostitis due to dental caries; in the latter condition, however, the bone is pretty sure to be attacked, in any case the decayed teeth would have to be extracted and the progress of events would speedily clear up the diagnosis. The prognosis may be gathered from what has been said in describing the course of the disease and the different types which it may assume. In general terms it may be stated that the acuter the onset the graver is the outlook; and, on the other hand, the slower the course and the more localised the process the more likely is the disease to yield to treatment. Besse's figures show that in the ordinary cervico-facial form the average mortality is about 8 per cent., but when the upper jaw is the seat of disease the fatality is much greater. Of 16 cases of this description under Poncet 8 died. Jirou gives the following death-rates for the different forms of actinomycosis: of face and neck, 11 per cent.; thoraco-pulmonary, 83 per cent.; abdominal, 71 per cent.; and cerebral, 100 per cent.

Actinomycosis can often, as in the case which forms the basis of this communication, be cured by the internal administration of iodide of potassium alone. It is remarkable that the use of this drug, which is now known to be almost as certain a specific in actinomycosis as it is in tertiary syphilis, should still be unfamiliar to English practitioners. It is not mentioned at all in some recent works on diseases of the skin, including my own, and it is referred to only in the most cursory manner in text-books of surgery published within the last twelve months. It was first used in veterinary medicine by Nocard[35] in 1885, and also by Thomassen[36] of Utrecht. In Chicago, out of 185 oxen suffering from the disease, 71 were cured by iodide of potassium.[37] In the human subject it seems to have been first used by Netter.[38] It was soon afterwards successfully employed by Buzzi and Galli-Vallerio.[39] In Holland instances of cure by means of this remedy have been recorded by Van Itelson of Leyden, Salzer of Utrecht, and others. In France it has been successful in the hands of Meunier,[40] Gaube,[41] Jaboulay,[42] Dubreuilh and Frèche,[43] Legrain,[44] Monestié,[45] and Duguet;[46] and Poncet and his pupils Jirou and Besse bear emphatic testimony to its value. Rydygier[47] of Warsaw also speaks favourably of its use; in Denmark it has been used successfully by Schon;[48] and in America it has been tried with excellent results by Van Arsdale.[49] Milton[50] cured a case in the Kasr-el-Aini Hospital in Egypt, the first recorded in that country, with large doses of iodide. In this country Pringle[51] has obtained very encouraging results in one case with the

iodide, although he did not give it in full doses. Iodide of potassium has also been used with success by Ward of Leeds.[52] I have heard privately of a few other cases in which the treatment has been successful in some London hospitals, but they are still unpublished.

The mode of action of the drug in actinomycosis is not yet clearly understood. It does not seem to kill or even injure the parasite. Nocard found that a solution of 1 per cent. of iodide of potassium did not check the growth of cultures in an artificial nutrient medium. Netter believes that the remedy has a specific action on the anatomical elements, increasing their power of resistance and thus strengthening the organism in its struggle against the disease. However this may be there can be no doubt of its influence for good. It causes a rapid subsidence of the tumours and nodosities, the parasites are discharged through the sinuses or are absorbed, and ulcerated surfaces heal. In the case above recorded the therapeutic effect was even more striking than that of the drug in tertiary syphilis. The earlier the administration of the iodide is begun the surer and speedier is its action. In order to get the full effect it must be given in full doses. Beginning with ten or fifteen grains three times a day, it should be steadily pushed to twenty, thirty, forty grains, and even larger doses if necessary. The more active the disease the more energetic must be the medication. As a rule the drug is well borne, but if it comes to be what may be called a struggle for life between the remedy and the disease any inconvenience likely to be caused by the former is preferable to the almost certainly fatal effect of the latter. Poncet usually combines local applications of iodide of potassium with its internal administration. He injects a 1 in 100 solution into the sinuses and fistulæ or inserts pencils of the iodide resembling those often used for the application of iodoform. Others, as Rydygier, combine interstitial injections of a 1 in 100 solution into the mass with internal medication by iodide of potassium. The average duration of treatment by the internal administration of iodide of potassium is from six weeks to two months. Although the drug may almost be considered a specific it must not be accounted infallible. Poncet records three cases under his own care in which the disease went steadily on to a fatal issue, apparently uncontrolled by the remedy. Dr. D. N. Knox[55] has quite recently reported a case in which the drug was equally useless. On the other hand, in estimating the therapeutic efficacy of the iodide it must be borne in mind that there are cases of benign type which have a natural tendency to end in cure. Arsenic has been used alone or combined with iodide of potassium in cases of abdominal actinomycosis (perityphlitis actinomycotica) by Ammendorp[54] and Tscherning,[53] both of Copenhagen. In a case under Darier's care, in which the affection was limited to the soft parts of the face, a cure was effected by electro-chemical treatment applied by Gautier;[56] a solution of iodide of potassium was injected into the diseased tissues, and a current was then passed through so as to decompose the substance and thus utilise the antiseptic power of iodine in its nascent state. Tuberculin was used successfully in one case by Billroth,[57] and Ziegler[58] has had good results with the same remedy. Thyroid extract has been employed by Pringle in two cases; one[59] improved remarkably under the treatment; in the other[60] the remedy did good at first, but had to be discontinued on account of the untoward symptoms caused by it. In many cases the internal medication must be supplemented by surgical measures. Suppurative foci must be laid open and drained; the walls of chronic sinuses and cavities must be curetted and purified and necrosed bone must be removed; ulcers and wounds must be dealt with on ordinary antiseptic principles. It is hardly within my province, however, to go into details on this subject.

A word or two respecting prophylaxis may not be out of place. Arloing recommends that all animals suffering from actinomycosis in however mild a form should be slaughtered. If this measure is considered too drastic at least the meat from such animals should be carefully inspected, and the same precautions should be adopted in the cooking of it as are enjoined by Dr. Woodhead[61] relative to tuberculous meat. Milk from animals with "lumpy jaw" or "wooden tongue" should be boiled before use. A word of caution may be added as to the danger of chewing bits of grass or straw, as many people besides ostlers and Lord Palmerston (see Leech's caricatures of that statesman *passim*) are in the habit of doing. As for picking the teeth or clearing out carious cavities with straw—a procedure I have known to be adopted—it can only be described as flying in the face of Providence.

Summaries of what is known about actinomycosis are given by L. Bérard in the Gazette des Hôpitaux of Feb. 29th and March 7th, 1896 (with a copious bibliography), and by Nacciarone in the Riforma Medica, March 23rd, 1896.

Harley-street, W.

THE SYMPTOMS AND TREATMENT OF DISEASES OF THE ATTIC (UPPER PART OF THE MIDDLE EAR).

BY ADOLPH BRONNER, M.D.,

SURGEON TO THE BRADFORD EYE AND EAR HOSPITAL; LARYNGOLOGIST TO BRADFORD INFIRMARY.

BEFORE discussing this important subject it would, perhaps, not be out of place to explain and describe a few of the terms used. The attic—also called recessus epitympanicus, or aditus ad antrum, or Kuppelraum—is the upper part of the middle ear and contains the head of the malleus and the greater part of the incus. The tegmen tympani forms the roof and Shrapnell's membrane and a ridge of bone above it form the outer wall. It is divided into several cavities by the ligaments of the malleus and the incus and by folds of mucous membrane, which connect the ossicles with the walls of the attic. These vary to a considerable extent. Shrapnell's membrane is the upper part of the membrana tympani. It is thinner than the lower part or pars tensa, as it consists only of two layers (integumentary and mucous) and lacks the middle or fibrous layer. The attic plays a very important part in connexion with the diseases of the middle ear and mastoid antrum, partly because of its position, as it is practically the connecting link between these two cavities, and partly because of its contents and the arrangement of the same. Inflammation of the middle ear can very readily spread into the attic, and when it has once got into the various cavities it rarely heals spontaneously. This explains why the ossicles and walls of the attic are so frequently diseased. Often there is an accumulation of thickened exudation or pus, or we may find a genuine cholesteatoma. Wall found caseous matter in the attic in forty-four out of sixty-five cases of perforation of Shrapnell's membrane. My own experience quite agrees with these figures. It is difficult to localise the exact seat of the disease. The position of the perforation, however, helps us

[61] See Report of Royal Commission on Tuberculosis.

Digitized by Google

to some extent. If it is over the short process of the malleus then the head of the malleus is affected; if behind, the long process of the incus; whereas if the walls of the attic are diseased there is a large perforation in the upper part of Shrapnell's membrane. In all cases of perforation of the lower part of the membrana tympani, in which ordinary treatment (removal of granulations, local applications, &c.) has failed to effect a cure in a few months, we can be nearly sure that the attic is diseased—especially in adults—and perhaps also the mastoid cells. In adults we nearly always find that if the mastoid cells are affected the attic is also diseased. This is of great importance in the surgical treatment of the diseased mastoid process. It is the reason why Schwartz's original operation is frequently so unsuccessful: because we do not lay open and treat the diseased attic. This naturally keeps up the otorrhœa and often causes recurrence of the mastoid disease.

The symptoms of disease of the attic are chiefly objective. We in most cases find perforation of Shrapnell's membrane or of the pars pensa with or without granulations. We can have simple accumulation of pus, or a cholesteatoma, or caries of the ossicles or of the wall of the attic. Frequently granulation tissue projects through the perforation of Shrapnell's membrane and may attain large dimensions. Often we find a small, dark crust which covers the perforation and which is often mistaken for cerumen. These cases are frequently overlooked, and yet it is of great importance that they should be diagnosed, as the crust naturally causes retention of pus. It very readily re-forms when removed. We can have disease of the attic without perforation of the membrana tympani. In my experience these cases are not at all uncommon. The patient complains of pain in or above the ear, of a feeling of fulness, not always of deafness. We find redness and slight bulging of Shrapnell's membrane or of the upper part of the external meatus. Frequently in chronic cases there is swelling above the auricle, extending forwards and backwards, often as far as the apex of the mastoid process, and thus simulating disease of the antrum. I have recently operated on a man aged thirty years who for twenty years has had discharge from the right ear. On three occasions he had Wilde's incision performed for mastoid abscess. I was much surprised to find the mastoid process apparently normal and a large cholesteatoma of the attic.

Pain, of course, is a common symptom and it varies with the nature of the disease. I have seen several cases in which the only symptoms were frequent attacks of dull, aching pain, with slight bulging of Shrapnell's membrane, with no marked deafness. I incised, found caseous matter, and scraped and syringed out with excellent results. Often there are shooting pains which radiate chiefly upwards and forwards. In all cases of mastoid disease with pain above and in front of the ear, especially if there is any swelling there, we should carefully examine the attic. As regards treatment, I think that we should be guided by ordinary surgical principles: enlarge the perforation, excise part of the membrana tympani (if necessary), remove any granulations and caseous matter by the curette and the syringe, and apply chromic acid, iodoform, aristol, &c., taking care, of course, that the perforation be kept well open. If the malleus or incus is diseased and loose they can easily be removed. If they are firmly attached or difficult to find, it is best to wait awhile before attempting to remove them. We then do not incur the great risk of damaging the stapes or the facial or semicircular canals. I use Delstanche's or Hartmann's or Milligan's irrigator for washing out the attic and Delstanche's new curette for removing the malleus. I believe that if these simple methods of treatment were more thoroughly carried out we should not hear so much of the wonderful operations for removing the ossicles under chloroform or of opening up the attic. Out of forty-two private cases of perforation of Shrapnell's membrane I have only twice removed the ossicles under chloroform and opened up the attic in ten cases. In the remaining thirty cases free incision, syringing, and scraping effected a cure. The incus is often dislocated or absent.

If these ordinary methods and the removal of the ossicles fail to effect a cure, or if the external meatus is too narrow to apply local treatment, we must open up and explore the attic. I make a long incision behind and round the top of the ear down to the tragus, cut through the external meatus, and pull the whole of the ear downwards. The wound is dressed from above and allowed to heal from below. There is very little deformity, and a much better view is retained of the diseased parts during the period of healing. If a permanent fistula has to be retained it is for obvious reasons much more desirable that this should be above and not behind the ear. I always remove the outer wall of the attic and the posterior wall of the external meatus with the chisel. Macewen, Barr, and others recommend the use of the burr and dental engine. I have not yet been able to find burrs which bite properly on the hard bone, and the operation thus becomes very tedious. We frequently find a number of mastoid cells on a level with the attic. In all operations these should most carefully be looked for, and if necessary opened up and scraped. If they are overlooked the disease is sure to recur.

The after-treatment is often very tedious. I have generally kept the outside wound open for a month or two, and if necessary allowed a permanent opening to form. In a few recent cases I have adopted the method of incising the external meatus and forming it into a flap or flaps, or of excising part of the meatus. A very large external meatus is thus obtained and the diseased parts can easily be watched through it; apply remedies locally, and thus allow the outside wound to heal up at once. I apply iodoform for a few days after the operation and then use aristol or europhen. Iodoform has a tendency to cause increased growth of granulation tissue, which blocks up the field of operation.

The facts to which I should have liked to draw particular attention are: (1) that localised disease of the attic is very common—more so than is generally supposed—and that it may occur without perforation of the membrana tympani; (2) that in cases of chronic otorrhœa which have for some time resisted the ordinary methods of treatment, and in disease of the mastoid antrum in adults, the attic is nearly always affected; (3) that in all cases of disease of the attic we should adopt ordinary simple surgical treatment before removing the ossicles under chloroform or opening up the attic; (4) that in opening up the attic we should prolong the incision over the top of the auricle downwards to the tragus and treat the wound from above; (5) that in suitable cases the external meatus should be partly excised or incised, and flaps formed and the outer wound allowed to heal up at once; and (6) that we should always remove the outer wall of the attic and the posterior wall of the external meatus and carefully look for any mastoid cells which may be on a level with the attic.

Bradford.

OPERATION FOR THE CURE OF VESICO-VAGINAL FISTULA.

BY J. RUTHERFORD MORISON, F.R.C.S. ENG.,

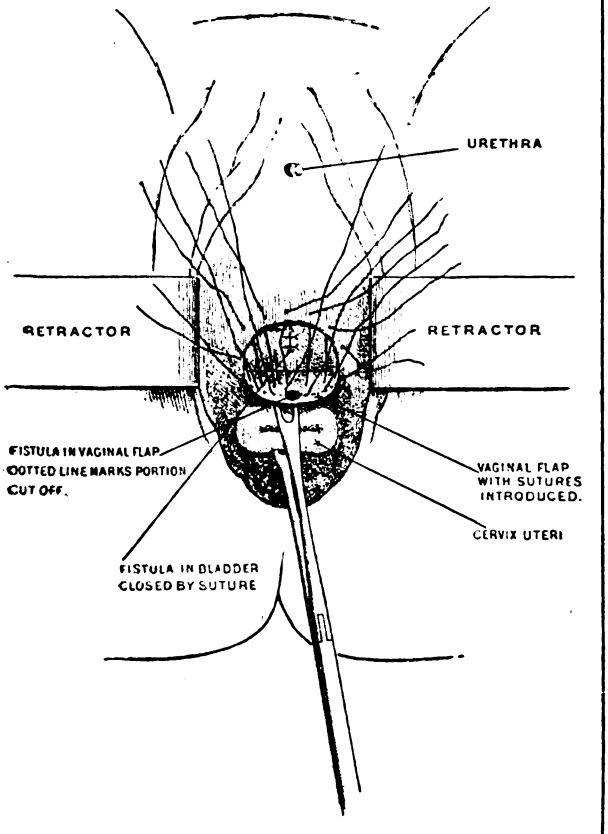
SENIOR ASSISTANT SURGEON TO THE ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

So far as I know two operations are performed for the cure of vesico-vaginal fistula—(1) the ordinary operation, and (2) Mr. Lawson Tait's operation. In the latter the edges of the fistula are split all round, the bladder edges turned forward and the vaginal edges backwards, and the raw surfaces between the two are brought into apposition by sutures limited to the freshened areas. The description of both operations is as simple as the execution of them is difficult. The chief risk of both is that one or more sutures may be left projecting into the bladder, and there are several objections to either. To bring linear surfaces into such accurate contact that no leakage can occur is too much to expect from an ordinary operator; and if this difficulty is overcome the sutures are apt to cause trouble from the dragging to which they are subjected by the normally tense vaginal wall. Then the thick unyielding vaginal wall, the larger size of the opening on the bladder side, and the depth of the bladder wound make satisfactory closure of the fistula in the bladder without perforation almost impossible. Some leakage into the wound from the bladder side is more than likely to occur. My notion is that to operate in these cases with the greatest probability of success the same principle must be applied that has revolutionised the treatment of intestinal fistula. The opening of the bladder must, like that in the intestines, be freely exposed, and in the former, as in the latter, complete closure of the visceral opening should be regarded as the key to a successful result. There are two anatomical points which may be noticed as bearing upon my operation: (1) that the

Digitized by Google

thick-walled vagina is separated from the thin-walled bladder by a layer of cellular tissue, usually so friable that a finger suffices to separate one from the other; and (2) that the blood-supply comes to the vaginal walls from every quarter, so that flaps with a good base may, without fear of sloughing, be reflected in any direction convenient.

CASE 1.—A woman twenty-four years of age was placed under my care by Dr. Proud of Maryport in August, 1895. Her history was that on April 15th, 1895, she was delivered by instruments after a hard labour lasting twenty-four hours and that the child was dead. After her confinement she noticed that she had no desire to micturate unless she coughed, but this caused her no alarm, for she did not know that anything was wrong. When she began to move about her urine constantly dribbled away, but when she was in bed about two ounces could be retained. In a letter which I had from Dr. Proud he said that the fistula was discovered by injecting milk into the bladder and watching it escape through the vagina. This device, although old, is so ingenious and easy of application that it is well worth remembering. On examinination the vagina at the upper part was found to be narrowed by cicatricial bands, especially behind. The cervix was small and eroded. About three-quarters of an inch from the cervix, in the centre of the anterior vaginal wall, was a rounded opening about the size of a split pea, which opened directly into the bladder. The operation was performed on Aug. 5th, 1895. A horseshoe-shaped flap was marked out on the anterior vaginal wall (see 1). The toe of the horseshoe included the fistula, and the heel which formed the base of the flap pointed to the cervix (1). The vaginal mucous membrane was divided with a knife,



the flap peeled off the bladder wall, and the opening into the bladder was fully exposed (2). All this separation was carried out with a finger and the blunt, closed ends of a pair of scissors, excepting round the fistula, where cicatricial tissue made the union between the bladder and the vagina very firm. The opening in the bladder was now closed by a fine continuous silk Lembert's suture, holding the muscular coats only (3). An ordinary surgical needle and needle-holder served for the purpose, being easy to apply, for the bladder wall was slack and there was no tension on the suture. The bladder was now tested by injection and proved to be water-tight. The operation was completed by cutting off the tip of the vaginal flap, including the fistulous opening into it, and adjusting the flap to the raw surface, where it was held by interrupted catgut sutures (4). The vagina was packed with iodoform gauze and a self-retaining catheter left in the bladder. The dressings and catheter were left undisturbed, except that the bladder was washed out thrice daily for the first week. On the eighth day the vaginal plug and catheter were removed. From beginning to end the patient had no trouble; the vaginal wound healed by first intention, the catgut sutures being absorbed, and she went home cured on the eleventh day. The opening in the vaginal flap in this case was cut off, but if it had been larger closure of it with a continuous catgut suture before replacing the flap would have been the better method of treating it.

CASE 2.—This was a woman forty-two years of age, mother of nine children, and a patient of Dr. Hume, to whom I am indebted for leave to publish the case and for the notes of it. Her trouble began after a bad confinement six years ago. She had been constantly wet since. A year before operation her last child was born. On examination a small fistulous opening was discovered in the anterior vaginal wall close to the cervix. On Nov. 18th, 1895, the operation described for Case 1 was performed by Dr. Hume. The opening in the bladder was closed with silk, the vaginal flap sutured with catgut, and the vagina plugged with iodoform gauze. The after-progress of the case is as follows. A catheter was used every four hours for the first five days. Afterwards the patient micturated unaided. She was discharged cured on Dec. 7th, 1895.

Note for reference to lettering in illustration.—1. Vaginal flap with sutures introduced. 2 and 3. Fistula in bladder closed by suture. 4. Fistula in vaginal flap; dotted line marks portion cut off. The figures refer to the figures in the text.

Newcastle-on-Tyne.

PULSATING EXOPHTHALMOS.

BY WALTER RIVINGTON, B.A., M.B. & M.S. LOND., F.R.C.S. ENG.,
CONSULTING SURGEON TO THE LONDON HOSPITAL.

THE LANCET of Jan. 27th, 1894, contained an interesting address on "Pulsating Exophthalmos—a Plea for Early Ligature," by Mr. George Edward Walker, F.R.C.S. Eng. In this address Mr. Walker advanced some opinions on the pathology and treatment of the affection with which I cannot entirely concur, and referred to a case of my own. At the time the paper appeared circumstances prevented me from taking notice of it, and I have been obliged to defer commenting upon it until I had leisure to refer to the full details of the other cases on which Mr. Walker relied for the support of the views which he enunciated. Pathologically Mr. Walker's main contention appears to be that, with the exception of some traumatic cases caused by the perforation of the carotid artery within the cavernous sinus by a stab with a pointed weapon or a splinter of bone, these cases of pulsating exophthalmos are due to aneurysms (I do not know whether he means circumscribed or fusiform aneurysms or both), and that such aneurysms before they have become ruptured are adequate to produce all the characteristic symptoms of intra-orbital aneurysm. Now this, I believe, is exactly what a circumscribed or a fusiform aneurysm of the internal carotid artery in the cavernous sinus is incapable of doing so long as it remains entire. It is not until the artery or the aneurysm ruptures and the arterial blood from it is pumped into the sinus and so driven along the veins of the orbit that the characteristic symptoms of "intra-orbital aneurysm" commence. An aneurysm of the internal carotid in the cavernous sinus or of the ophthalmic artery at its origin may produce pressure symptoms affecting particular nerves (third, fourth, fifth or sixth), symptoms of obstruction to the return of venous blood such as œdema of the lids and conjunctiva, hazy ulcerated cornea, or injection of the sclerotic and conjunctiva, but not the typical symptoms of intra-orbital aneurysm. After the most careful examination of the evidence afforded by all the published cases known to me I stated the conclusions at which I had arrived in my article in Heath's "Surgical Dictionary" (1886) as follows:

Digitized by Google

"1. Beyond question the great majority of the traumatic cases have been instances of endocranial arterio-venous communications due to wound or rupture of the internal carotid artery in the cavernous sinus. 2. Beyond question the great majority of the idiopathic cases have been instances of endocranial arterio-venous communications due to a rupture of an aneurysm of the carotid or of an atheromatous carotid in the cavernous sinus. 3. The occurrence of a circumscribed aneurysm of the ophthalmic artery or one of its branches, as a cause of the same symptoms as were exhibited in the cases of arterio-venous communication, rests at present solely on the laconic report of Guthrie. Moreover, aneurysm of the ophthalmic artery in the orbit is a very rare affection." The first two conclusions have been accepted save by Mr. Walker by surgeons and writers who have published cases since my paper was written. The third, so far as evidence is concerned, now requires some modification, because on Sept. 18th, 1886, Dr. Dempsey of Belfast published an extremely interesting and instructive case in which, combined with a fusiform aneurysm of the carotid artery in the cavernous sinus, there was an immense saccular aneurysm on the upper part of the ophthalmic artery capable of holding a mandarin orange. The carotid artery was tied, but the aneurysm of the ophthalmic artery burst into the eyeball and profuse hæmorrhage from the cornea and secondary hæmorrhage from the ligatured artery proved fatal on the forty-first day.

The cases adduced or referred to directly or indirectly by Mr. Walker in his address are twelve in number and may be briefly summarised.

CASE 1.—A female forty-two years of age under Mr. Walker. She fell into a deep cellar on Aug. 19th, 1893. The accident was followed by noise in the right ear, venous congestion, and protrusion of the right eye. Great impairment of vision and bruit. The right common carotid artery was tied by Mr. Puzey on Sept. 19th, 1893. The patient recovered and was cured of the aneurysmal affection, but the sight was not improved.

CASE 2.—A female thirty-three years of age under Mr. Walker. She had received a blow on the left ear from a man's fist and was seen on June 6th, 1878. The symptoms were similar to those in the last case, the eye being on the cheek and the cornea opaque. The left common carotid artery was tied on July 23rd. The patient was cured completely, sight being fully restored.

CASE 3.—A boy aged fifteen years under Mr. Walker. He had sustained a fall in Feb., 1886, and was seen by Mr. Walker on Aug. 2nd. There was protrusion of the right eye with aneurysmal symptoms. The parents refused assent to operation and consulted some London surgeons, who concurred in this decision. The local conditions remained stationary until Jan. 20th, 1887, when, going to a theatre, he got into a crush and was much alarmed and almost fainted. The pulsation and murmur ceased and did not return.

CASE 4.—A man aged thirty-seven years under Mr. Puzey[1] and seen by Mr. Walker. He fell off his horse in March 1888. Aneurysmal symptoms supervened on the left side. Digital compression failed. He would not submit to ligature till May, 1889, when the swelling in the left orbit was of the size of a Tangerine orange and there was marked pulsation in the branches of the ophthalmic vein. The result was similar to that in Case 1, the aneurysmal symptoms being removed, but sight not being regained. The cornea gave way in a month's time and the iris became adherent. Mr. Puzey quoted my views on the pathology of the affection with approval.

CASE 5.—My own case,[2] a fracture of the base of the skull followed by the symptoms of intra-orbital aneurysm and undoubtedly due to arterio-venous communication. Some comments of Mr. Walker on the case I will discuss presently.

CASE 6.—Dr. Dempsey's case,[3] already referred to as a case of aneurysm of the ophthalmic artery in the orbit.

CASE 7.—A male aged fourteen years under the care of Mr. T. Richard Williams and Dr. Robert Jones.[4] The patient received a kick on the left temple. This was followed by the usual symptoms of "intra-orbital aneurysm." The case was diagnosed as one of arterio-venous communication. The carotid was ligatured and a cure resulted.

In the discussion on this case at the Ophthalmological Society some other cases were referred to.

CASE 8.—A male under Mr. Wherry for fractured base of the skull followed by aneurysmal symptoms. The diagnosis was arterio-venous communication. Ligature of the carotid was performed; paralysis resulted, but the aneurysm itself improved, the bruit and proptosis being removed. The paralytic symptoms were attributed to the sudden cutting off of the blood supply from the damaged area of the brain.

CASES 9, 10, and 11.—Three cases under Mr. Tatham Thompson, two being traumatic and in children, and *intra-orbital not intra-cranial* arterio-venous communication being diagnosed. In one case the exophthalmos and bruit entirely disappeared after electrolysis and in the second there was a partial recovery after repeated electrolytic operations. The third case was that of a female aged forty-two years. Eleven months previously a sudden shock or "crashing noise" had occurred in a protracted fit of vomiting during pregnancy. The patient complained of distressing noise, especially when lying down. The bruit was well-marked over a considerable area and a distinct thrill was felt on palpation. Pressure on the carotid lessened the bruit. Vision was reduced to a perception of light. The patient would not agree to ligature of the carotid, and when last seen the condition remained unchanged. The diagnosis was arterio-venous communication in the cavernous sinus.

CASE 12.—A case referred to by Mr. Adams Frost, which he had shown to the Ophthalmological Society in 1883. Here there had been pulsation *in both orbits*, but it disappeared from one. The man was still able without difficulty to follow the occupation of a wheelwright.

The foregoing cases certainly lend no kind of support to Mr. Walker's view that ordinary aneurysm of the carotid artery in the cavernous sinus and not arterio-venous communication is the usual cause of the group of symptoms known as "intra-orbital aneurysm." He does not adduce the results of post-mortem examinations to prove his contention, but relies entirely upon arguments which in the face of the sudden onset of the symptoms, often with noise in the head, and the venous pulsation, and in the face of the pathological evidence in our possession demonstrating traumatic arterio-venous communications and in idiopathic cases, ruptured aneurysm, or aneurysm of the ophthalmic artery in the orbit, and one or two instances of venous obstruction I do not think it necessary to follow for the purpose of further refutation. But before concluding I must correct one or two misconceptions with regard to my own case contained in Mr. Walker's valuable address. For instance, Mr. Walker erroneously states that in this case "electrolysis (I suppose of the distended orbital vein) was used twice." On the contrary, it was not used at all. Owing, I suppose, to the misplacement of a comma by the printer—the comma being placed after the word "unsuccessfully" instead of "cases"—Mr. Walker has mistaken the remark which I made on this point for acceptance instead of rejection of the procedure. "Galvano-puncture, tried twice unsuccessfully in other cases, did not appear to be a suitable remedy for this form of aneurysm." The tone of Mr. Walker's remarks in regard to the injection of perchloride of iron is not so judicial as one could wish, and he has misconceived the bearing of my observations in one or two particulars. For instance, he says: "Acute cellulitis of the orbit set in and became so alarming that on the 15th, *after the propriety of a second injection had been considered*, the carotid artery was tied and, as a matter of course, things straightway began to mend. The failure of the perchloride of iron to cure is said to have been due to the fact that only five minims were injected instead of fifteen, but this hardly tallies with the fact that the lesser quantity seems to have started panophthalmitis." Why these italics, unless they are to emphasise the misconception involved in Mr. Walker's statement that the propriety of a second injection was *considered?* The proper course to alleviate the unexpected symptoms was reviewed in my own mind and I selected ligature of the carotid, whilst in my paper I simply stated *for the reader's information* why a second injection would not have been advisable. I object, therefore, to the italics, to the statement itself, and to the assumption of superiority involved in the phrase: "As a matter of course things straightway began to mend." Neither is there any incompatibility between my view that the injection of a few more minims of perchloride might have produced a better effect on the aneurysmal affection when cellulitis supervened after the injection of the smaller quantity. Anyone can understand that the injection of a few more minims of perchloride might have effected sufficient coagulation to stop the pulsation and bruit. Had the

Digitized by Google

vis a tergo thus been removed the severity of the cellulitis which I am inclined to attribute to a leakage through the puncture in the vein would certainly not have been increased and with prompt and complete coagulation inside the vessels might not have occurred at all.

Mr. Walker does not understand how pulsation of the globe could only last a few days and then disappear. The explanation seems to me to be that the first effect of the arterial blood being admitted into the ophthalmic vein and its branches was to produce pulsation of the globe, but as the blood passed more readily through the main channels of the vein and its external branches pressure on the globe was diminished and the pulsation became evident in the branches of the vein between the eyeball and the orbital margin instead of in the eyeball. There is one other observation of Mr. Walker in regard to my case to which I must allude. He speaks of temporisers resting their case on mine, but he omitted to mention the fact that I wrote strongly in favour of ligature and never advocated delay. From my own experience and the consideration of other cases I am disposed to agree with Mr. Walker—although not on the pathological grounds which he advances—that early ligature is, as a rule, the best treatment. Sight may not always be restored after ligature, but I think it will in the generality of cases and that early ligature offers the best and surest method of preventing impairment of vision. Leaving the case to itself may occasionally be followed by a spontaneous or accidental cure or some diminution in the severity of the symptoms, but generally the condition either remains stationary or becomes exacerbated with great impairment or loss of sight. Whilst objecting, therefore, to Mr. Walker's pathological doctrines, which appear to me to be heretical in the extreme on this subject, I am glad that I am in the main in accordance with him on the cardinal topic of the best form of treatment. Since the time of Mr. Nunnely, who did so much to advance our knowledge of the pathology of this interesting form of aneurysm, no one has had so large a clinical experience of cases exemplifying it as Mr. George Walker, and I cannot but heartily congratulate him on the fact that the successful results of his operations have prevented him from having the opportunity of seeing for himself that his view of the pathology of the affection is entirely unsupported by the actual conditions demonstrated by post-mortem examination.

Wimpole-street, W.

IMPACTED URETHRAL CALCULI.

BY ARTHUR COURT, M.B., B.C. CANTAB.

THE following cases of impacted urethral calculi seem to me to present sufficient interest to justify their being recorded.

CASE 1.—This patient was a girl seven years of age who was brought to me three years ago suffering from pain in the abdomen and frequency of micturition. The urine being alkaline and containing muco-pus she was treated for cystitis. One day she was seized with retention and I found an oblong phosphatic calculus impacted at the meatus. It was easily removed and the cystitis was soon better. The stone weighed nine grains. Last January she had another attack of retention and on passing a catheter I could not feel any calculus, but a few days afterwards she again suffered from retention and this time another calculus was removed from the meatus. It consisted of oxalate and phosphate of calcium with a soft core of the same materials intermixed. Sounding failed to reveal anything further and the girl is at present in good health.

CASE 2.—This patient was a man forty-seven years of age and married, his youngest child being nineteen years old. When quite a young man he had an attack of gonorrhœa, but was otherwise healthy up to nineteen years ago, when he met with an accident to the buttocks and perineal region and was for nine months unable to work. He states that no blood was lost from the urethra, but that a catheter was required to relieve the bladder. He cannot remember whether he had any difficulty in micturition previously to the injury. From time to time he had had a discharge of thick fluid from the urethra, a teaspoonful or so coming away on each occasion, and there had been great and increasing difficulty in micturition. Two years ago he was treated for piles. In the beginning of May, 1894, he indulged in large quantities of beer and the retention became almost complete, the pain on micturition being severe and the necessity frequent. When I saw him for the first time on May 19th his pulse was quick and his temperature normal. There was no discharge from the urethra and when he was requested to pass urine only a few drops escaped. It was clear, acid, and free from albumin and sugar. There was a distinct thickening in the perineum behind the scrotum, and the prostate gland as felt per rectum was slightly enlarged but not tender. The introduction of a No. 8 catheter was attempted, but it was arrested at a point corresponding with the thickening felt externally, and all the smaller-sized instruments were subsequently tried, including a No. 1 silver catheter, but nothing could be guided through the stricture without using undue force. A hot bath, a dose of opium, and a mixture of sulphate of magnesia and henbane were ordered, and on the morning of May 20th the patient's condition was much the same, the urine dribbling away when he strained, but in the evening the retention was complete and was attended by great pain. No elastic instrument could be passed, but after persevering for some time a No. 1 silver catheter went through the stricture and a rough grating sensation was communicated to it when overcoming the obstruction, so that I feared a false passage had been made; after the catheter was withdrawn about four drachms of thick muco-pus escaped. On May 21st the catheter was passed again and was retained all day, the same grating sensation being experienced. On the 22nd the No. 1 catheter was passed and was kept in. On the 23rd three small calculi came away, together with a large quantity of muco-pus; a No. 2 elastic catheter was introduced and retained for four hours. On the 24th three more calculi were expelled and a No. 2 catheter was tied in, but withdrawn on the 25th. On the 26th, as the patient had passed no urine since the previous day, a No. 2 catheter was passed through with some difficulty, the same grating sensation being felt as before. On the 27th a No. 3 catheter was passed and kept in for four hours; nine calculi followed the first attempt at micturition after its withdrawal. On the 28th a No. 3 instrument was passed, but no grating was felt. On the 29th a No. 3 bougie was retained for two hours and five more calculi followed its withdrawal. On the 30th the patient had retention all day and a No. 3 catheter was passed in the evening; about two ounces of muco-pus and three more calculi came away on the first attempt at micturition after its withdrawal. Between May 31st and June 6th bougies Nos. 4, 5, and 6 were passed. On June 6th while the patient was passing urine the stream suddenly ceased and he felt confident that another calculus was caught in the stricture, but I could feel nothing with a No. 5 bougie. On the 7th Nos. 5, 6, and 7 bougies were passed, but no calculus was felt, nor was there any grating. On the 8th a calculus was passed weighing a little over two grains. The stricture was subsequently dilated up to No. 12, although not without several relapses, and no more calculi were seen. The twenty-four calculi which were voided weighed twenty-six grains and are all similar in appearance and composition, being a mixture of calcium carbonate and phosphates.

CASE 3.—This patient was a pit lad aged eleven years. His father died from vesical calculus, and a sister is now under my care with renal colic and hæmaturia. Three years ago his mother noticed blood in his urine. He had typhoid fever in September, 1894, but he had not since then suffered from any pain or hæmaturia, and was quite well until midday on March 8th, 1896, when he found that micturition had become impossible. He was brought to me on the following day, not having passed urine for nearly twenty-four hours, and an oblong calculus (fixed transversely across the urethra) was then presenting at the meatus. It was easily removed with forceps, and immediately behind it was another calculus firmly fixed, which could not be removed until it had been broken up. Free urination promptly followed, and no other calculus could be detected in the bladder. The one which was removed entire weighed three grains. It was formed of uric acid with a nucleus of blood-clot.

Cases 1 and 3 are instances of the position in which calculi are most frequently arrested when they enter the urethra of children, and consequently they call for no further comment; but Case 2 is interesting because it is unusual for a man to have a stricture for nineteen years without permanent damage being done to his bladder or kidneys. The

Digitized by Google

grating felt on passing the catheters was no doubt due to their coming in contact with the calculi. The man had never before passed a calculus, and they seem to have been formed primarily in the prostate and then to have found their way into the pouch behind the stricture. The smaller stones came through the stricture first, and last of all the largest stone, which was evidently impacted in its first attempt at escape.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF RUPTURE OF THE UTERUS.

BY S. WILKINSON, M.R.C.S. ENG., L.R.C.P. LOND., L.M.S., L.M. COOMBE HOSPITAL, DUB.,
HONORARY SURGEON TO THE BIRKENHEAD LYING-IN HOSPITAL AND LADIES' CHARITY.

ON April 11th I was called to a woman whom I found in the following condition. She had very severe hæmorrhage, but no pains. The os admitted four fingers. She had placenta prævia centralis; the presentation was a vertex one and the head was very large. I separated the placenta as far as I could and in the meantime sent for an assistant to administer chloroform. Under the anæsthetic I easily obtained possession of a foot by separating one side of the placenta and brought it down through the os. As there were no pains I made traction on the foot with a cloth for about twenty minutes or half an hour. As the bleeding continued and there were still no pains I brought down the second foot and left the body for a little while in the os. I was then able to bring down the arms at short intervals, and, finally, after another wait, I delivered the head with face posteriorly and to the right. The hæmorrhage then ceased, and as I felt the placenta loose in the vagina I removed it with my fingers. Chloroform was given only at intervals and was ceased before the delivery of the head. Six drachms were given. The patient rallied, took some ergot, and assisted us with the placing of the binder and asked if all was over. She then became restless, and after about twenty minutes we saw that death was threatening and informed the friends. The restlessness had brought on fresh hæmorrhage. More ergot was given and ice was placed in the vagina, and the uterus felt for from the outside. Owing to the abdominal fat, however, it could not be felt. The pulse was 96 and hardly to be perceived, partly on account of the super-imposed fat. The patient died two minutes after we had informed her friends. No transfusion apparatus was at hand. The friends, supposing that she had died under chloroform, charged us with her death, and, becoming maniacal, assaulted us. They seized the ornaments and attempted to strike us. The midwife (who sent for help immediately on seeing the case) was seized and would have been hurt but for our interference. At last we were obliged to send for the police to assist us to recover our belongings, and extricate the midwife from the corner of the room where she was penned up. It was reported to the police and to the whole neighbourhood that we had murdered the woman with chloroform. On this account I thought it best that an inquest should be held; otherwise I should have given a certificate.

At the necropsy a rupture of the cervical and uterine tissues was found four inches in length and opening into the right broad ligament. The extravasated blood separated the layers of this, and I believe that during the subsequent restlessness the peritoneal covering burst, as was found. The immediate cause of death was hæmorrhage. The delivery took me about an hour and a half to accomplish, during which time bleeding continued at intervals. After the arms were brought down I felt the os and it was then intact. The rupture, which I did not suspect, must have been caused by the passage of the large head, probably by the face (which was born first) passing over that site. The papers had the case reported as "Death under chloroform," but the resumed inquest entirely relieved me from this charge, though the report has certainly done me harm.

Birkenhead.

*** Mr. Wilkinson's case affords a very good example of the reckless allegations which get into the public press concerning the use of anæsthetics. To report this death as one of "death under chloroform" was entirely unjustifiable. Looking at the facts of the case it may be questioned whether, having brought the leg down, it would not have been better to have waited, giving ergot meantime, until pains came on, which must have happened sooner or later.—ED. L.

THE LOCAL TREATMENT OF DIPHTHERIA WITH SODIUM HYPOSULPHITE.

BY HENRY A. WICKERS, L.R.C.P. LOND., M.R.C.S. ENG.

I HAVE for some time been using a solution of sodium hyposulphite as a local application in diphtheria and have been well satisfied with the results, three or four applications having generally been sufficient to clear away the false membrane. The solution is prepared for use by mixing equal parts of pure glycerine and a saturated solution of hyposulphite of sodium in water and is applied with a brush to the exudation and inflamed fauces once or twice daily or as often as may be deemed necessary. The glycerine by its adhesiveness keeps the solution longer in contact and also by its well-known local action helps to relieve that engorgement of the mucous membrane which seems especially favourable to the growth of exudation. It is probable that the hyposulphite has a continuing action as a germicide in the following manner: chemical decomposition is first set up by contact with the acid secretions of the mouth and throat, sulphur and sulphurous acid in a nascent state being set free; the latter being gradually converted by oxidation into sulphuric acid would in the same manner decompose further portions of unchanged hyposulphite, and so on until the hyposulphite was exhausted. Of course, this local treatment will not interfere with the general treatment, which must be adapted to the necessities of each individual case.

Upper Tollington-park, N.

A CASE OF ANTIPYRIN ERUPTION.

BY H. W. WEBBER, M.D. LOND.

THE patient was a woman aged fifty-three years who had two months previously undergone supra-vaginal amputation of the cervix uteri for cancer. On Dec. 7th, 1895, I found the entire surface of her body covered with a copious eruption exactly resembling in appearance that of a severe case of measles; the face and eyelids were also swollen. The temperature was 101·4° F. and the pulse 102. She had been taking ten-grain powders of antipyrin twice daily for the previous three weeks for the relief of pain extending down the right thigh. These had produced no ill effect, but it appeared that on the evening of Dec. 5th she had eaten some unwholesome food, the results of which no doubt interfered with the proper elimination of the drug. Three grains of calomel and a mixture of ammonium acetate were prescribed, and the next morning the skin was almost free from eruption, the swelling of the face had subsided, and the temperature had fallen to 98°. The antipyrin was omitted and pills containing a quarter of a grain of morphia were substituted. Finding, however, that these did not relieve the pain so well as the antipyrin had done, after a few days the patient re-commenced taking the powders. After the second dose swelling and redness of the face came on and she had again to leave them off. No symptoms of cardiac depression appeared to be produced by the drug in this case.

NORTH-EASTERN HOSPITAL FOR CHILDREN.

A CASE OF UNILATERAL BRONCHIECTASIS TREATED BY RESECTION OF A RIB AND PARACENTESIS.

(Under the care of Dr. W. A. WILLS.)

THIS case is one which serves well to draw attention to the peculiarities presented by some cases of bronchiectasis and the not unusual difficulties encountered in their treatment whether by medical or surgical means. There are such obstacles at times to the formation of an exact diagnosis during life that it is possible some surgeons have taken too favourable a view of the advantages of pulmonary incision and the insertion of a drainage-tube. In this division of surgery, as in others, very much depends however on the selection of the case and the medical attendant's judgment as to the best time for operation. There is sometimes, perhaps, too great a tendency to postpone operation. The questions which suggest themselves on perusal of the case are fully discussed by Dr. Wills whose remarks we commend to the attention of our readers. For the notes of the case and the report of the post-mortem examination we are indebted to Mr. G. M. Edwards, M.B. Cantab., late house physician.

A thin, miserable-looking boy nine years of age was admitted into the North-Eastern Hospital for Children, Hackney, on March 13th, 1895, for chronic cough accompanied by profuse and offensive expectoration. The family history gave no record of phthisis on either side. Both parents at that time were alive and healthy. The boy was stated to have been "wasting and coughing" for about two years, for the last few months of which his breath and expectoration had been so offensive that his mother could hardly bear to be in the same room with him. He had had measles when two or three years old, but no other illnesses. No history of any inhalation of a foreign body was obtainable.

On his admission to hospital the patient was found to be a pale, emaciated boy, very dirty, with several impetiginous sores about his body. The ends of the fingers and toes were of a bluish colour and markedly clubbed. The temperature was 99·2° F. The chest was thinly covered and markedly deformed, the sternum being unduly prominent and the lower ribs much flattened laterally. The two sides were symmetrical. The respiratory movements were much modified, elevation being excessive, and expansion almost absent. The percussion-note over the whole of the left chest was hyper-resonant. On the right side, in front from the clavicle to the fourth rib, the percussion-note was absolutely dull, but over the remainder it was impaired. Posteriorly there was impaired resonance over the upper half and absolute dulness over the lower half of the same lung. On auscultation the breath sounds over the upper half of the right lung, both in front and behind, were tubular in character, and accompanied by numerous coarse râles heard both with inspiration and expiration. In the upper part of the axilla the sounds were almost cavernous and the râles very numerous, some bubbling and some metallic in character. Over the lower half of the lung the breath sounds were very weak and distant, and at the base posteriorly they were inaudible. Over the apex anteriorly and in the upper part of the axilla there was well-marked whispering pectoriloquy. Breathing over the left lung was everywhere harshly vesicular and free from adventitious sounds. Cardiac dulness was absent; impulse could not be felt. The heart sounds were normal in quality and position, and the pulse was 84 and regular. The breath was very offensive, but the tongue was fairly clean. The bowels were regular and the appetite was fair. The abdomen was rather prominent; the liver was enlarged, its edge being three fingers' breadth below the costal margin, and the spleen was slightly enlarged. The urine contained a large quantity of albumen, The patient was ordered a mixture of carbonate of ammonia, ether, oil of turpentine, and chloroform water; and also to wear at intervals a respirator charged with creosote.

On the 20th, seven days after admission, the breath was slightly less offensive. The sputum was very profuse and offensive, coming up in large quantities after a paroxysm of coughing. These paroxysms occurred five or six times in the twenty-four hours. In the intervals between these the boy was comfortable. There was no night sweating and the patient was bright and cheerful, The temperature kept about normal. On the 30th the patient's general condition remained unaltered. The sputum averaged from eight to ten ounces in the twenty-four hours. After standing it separated into three layers, the lowest being almost pure pus, the middle a fairly clear fluid, and the uppermost frothy and fermenting. Beyond slight variations in the extent of area over which whispering pectoriloquy was obtainable the physical signs remained unaltered. At the beginning of April the temperature ran a somewhat higher course, averaging about 99·0°. On April 16th, the physical signs continuing unchanged and pointing apparently to the presence of a cavity in the upper part of the right upper lobe, and there having been no diminution in the fœtor or quantity of the sputum as a result of the treatment, and tubercle bacilli being apparently absent, Dr. Wills asked Mr. Bilton Pollard to see the boy with a view to attempting drainage by surgical means. On the 18th it was decided by Dr. Wills and Mr. Pollard to try operative measures. The temperature at that time ranged daily between 98° and 101°. For a week daily observations were taken and marked on the boy's chest as to the situation and extent of the supposed cavity, this being mapped out as occupying the second and third interspaces in front and extending outwards to the upper part of the right axilla. On the afternoon of the 27th the boy was taken to the operating theatre, and anæsthetised. Mr. Pollard then resected a portion of the third rib in the axilla and found the visceral and parietal layers of the pleura adherent at this point. With a trocar and cannula a number of exploratory punctures were then made into the lung in the direction of the supposed cavity, and finally into different parts of the affected apex; none of these punctures, however, resulted in the discovery of any cavity, nor did any pus appear in the cannula. The wound was then lightly packed with iodoform gauze, and sal alembroth gauze and wool dressings being applied the patient was sent back to bed. During the whole operation the boy was kept lying well on the affected side to obviate the flow of pus from the diseased lung into the bronchi of the healthy lung. Care was also taken to keep him in this position until he had quite recovered consciousness. Throughout the operation an almost continuous stream of horribly offensive pus trickled from the mouth and nose, this towards the end of the operation being blood-stained. The boy took the anæsthetic (chloroform) well. On the 28th the temperature in the morning was 99·8°. The sputum was brightly blood-stained. The patient seemed none the worse for the operation. On the morning of the 29th he was not quite so well. The pulse was 108 and the temperature 101·2°. The wound was healthy. There was no discharge. On May 1st the temperature was 101·2°, the pulse 112, and the respirations were 30. The sputum was rusty. The cough was frequent and the patient was decidedly worse. During the following night the temperature reached 103·4°. On the 2nd the morning temperature was 100°, the pulse 128, and the respirations were 40. The boy was much worse and was evidently sinking. Early in the morning of the 3rd he became delirious, the temperature being 101·8° and the pulse 140. Death took place at 4.30 P.M.

Necropsy.—The body was found to be emaciated. There was a surgical wound in the right axilla leading to an opening through the chest-wall into the lung. This opening was formed by the resection of a portion of the third rib. The right pleura was adherent generally over the upper half of the lung, but fairly free below. The right lung was small and shrunken, dark reddish-brown in colour, and of a tough leathery consistence, sinking in water and quite airless. On section it was found to be consolidated from apex to base; the distinction between the lobes was quite lost. The bronchial tubes were all dilated and had thick, tough walls; the dilatation was regular and no tendency to

Digitized by Google

sacculation was seen anywhere, the result being a series of branching tunnels varying in size from a crowquill to that of the little finger. The tubes in the upper half of the lung contained fluid pus, but towards the base the contents became thicker and thicker, the lowermost being blocked up with a thick, cheesy, and excessively fœtid material which could hardly be squeezed out of them. The left lung was large and showed marked emphysema, but was otherwise quite normal. The liver and kidneys were extremely fatty. The brain was not examined.

Remarks by Dr. WILLS.—I have reported this case of operation on a patient suffering from bronchiectasis for two reasons—first, because even now the number of recorded operations is not very great; and, secondly, because it well illustrates the difficulty of diagnosis which seems to be ever present in persons suffering from this complaint. In this instance the mistake in diagnosis consisted in the conclusion that there was a single definite cavity which could be reached surgically, whereas there was general bronchial dilatation, but no specially dilated bronchus to which the term cavity could be applied, and the physical signs of a cavity had been produced by consolidated lung surrounding a series of branching bronchial channels. Why the signs of excavation should have been localised to a spot at the upper part of the axilla, where the conditions giving rise to such physical signs appear to have been present throughout the lung, I confess I cannot now understand. That the boy was suffering from bronchiectasis and not phthisis was tolerably clear from the unilateral nature of the physical signs—the character of the sputum, the manner of its expulsion, and the absence of tubercle bacilli and to some extent from the history of the onset. There seemed no reason to suppose that the affection originated from a foreign body inhaled into the lung, as there was no account of such an accident having occurred, and the part of the lung apparently most affected being above rather than below the level of the main bronchus also made it unlikely that the cause was of this nature.

That there is often much difficulty in coming to a correct conclusion as to the exact condition present in the chest of patients with symptoms such as those above described is well shown by the discussion which took place on the paper by Dr. C. T. Williams and Mr. Godlee describing two cases of bronchiectasis treated by tapping and drainage,[1] which is referred to again shortly. Dr. Goodhart described a case of unilateral general bronchiectasis and localised empyema secondary to the inhalation of a pea into the bronchus, which he mistook for pleural effusion. In another case the side affected with bronchiectasis was thought to be the seat of pneumonia. Dr. Percy Kidd quoted a case where bronchiectasis was thought to be present in only one lung, but where it was afterwards proved to be double. He referred to the difficulty in deciding the existence of pleural adhesions. Dr. Cayley emphasised the importance of the existence of solid lung surrounding the cavity and its probable association with pleural adhesions. He also remarked on the liability to abscess of the brain in these cases. Dr. Bies thought the danger from septic poisoning so great that an operation should always be considered. Dr. Barlow and Dr. Coupland quoted similar cases to Dr. Goodhart's and Mr. Gould referred to the difficulty of determining the relation of the cavity to the spot where the physical signs are most marked, stating that he thought preliminary aspiration was a necessary step in diagnosis. These remarks appear to me to show very clearly how great are the practical difficulties the physician meets with when attempting to decide if a particular case is a suitable one for operation and in selecting the most suitable spot for the operation.

Surgical proceedings have been undertaken now in a sufficient number of cases to enable one to appreciate the advantages and disadvantages of such treatment. It may be interesting to shortly summarise a few of these cases. Dr. C. T. Williams[2] describes a case of bronchiectasis affecting the right lung generally, but with one specially large saccule in the lower and sternal part of the upper lobe. This was tapped after making a skin flap. Diminution of expectoration occurred for a few days, but then symptoms of pyæmia came on, and death occurred about six weeks after the operation. Dr. Williams and Mr. Godlee report two cases.[3] In one, a man aged sixty-seven years, the disease was quite localised and the result very satisfactory; in the other, a woman aged twenty-one years, the bronchiectasis was more generalised, and here the surgical treatment was more difficult and the effect less successful. Another case was also mentioned of a boy aged thirteen years with unilateral but somewhat extensive bronchiectasis, where a cavity was reached by puncturing to a depth of about four and a half inches. The result two years later was fair. Two other cases under Dr. Williams were also referred to in which death occurred shortly after the operation. His conclusions are that the operation is indicated—(1) where antiseptic treatment had failed and death from septic pneumonia appeared imminent, and (2) where the bronchiectases are confined to one lung, are in the lower lobe, and the overlying pleura is adherent. Dr. Douglas Powell[4] relates the case of a man aged forty-nine years with several bronchiectatic cavities in the lower lobe of the right lung. Mr. Lyell opened the lowest of these after finding pus by exploration in the eighth intercostal space. The patient was *well turned on the opposite side* during the operation. There was free drainage for a time and much improvement, but afterwards great difficulty in maintaining drainage. The man got gradually weaker, pleuro-pneumonia (? infective) affected the other lung, and he died. Post mortem it appeared that the lowest of several intercommunicating bronchiectatic cavities had been tapped, and that as the lung contracted the drainage had been interfered with. In the remarks on this case stress is laid on the difficulty in diagnosing between bronchiectasis and empyema, and Dr. Powell emphasises the importance of bulging of the chest-wall and distension of the interspaces in empyema as against flattening and retraction in bronchiectasis. He considers it desirable to operate over the centre of the physical signs, not over the lowest point. With regard to apex cavities Dr. Powell says the advisability of operating is doubtful, as from their position the drainage from them is efficient without operation, but he admits that the symptoms are sometimes ameliorated. It seems likely that this improvement is due to the absence of irritation of the neighbouring bronchi by the fœtid secretion in its course towards the main bronchi previously to its expulsion by coughing. Dr. Biss[5] reports a similar operation on a man aged thirty-two years, suffering from multilocular bronchiectasis of the right lung. In this case, also, the patient was turned on to the left side "as far as could be done without embarrassment to his breathing." There were firm pleural adhesions and much pleural thickening. The cavities contained a quantity of mortary, fœtid material; one of the largest cavities was tapped. The cardiac apex was displaced one inch to the left, and for the first fortnight the patient was under observation the physical signs were those of fluid. For a time there was considerable improvement in the lung symptoms, but death occurred a month after the operation from infective brain abscess and meningitis. Mr. Rickman Godlee, in a series of lectures on the Surgery of the Lungs,[6] quotes a very similar case to mine, where the physical signs were clearly those of a cavity beneath the fourth right intercostal space in front. A puncture was made with a trocar, but no pus was found. However, an incision was made, but no cavity or pus was found. The patient was lost sight of after the wound was healed. Mr. Godlee mentions the importance of thoroughly exploring before proceeding further. He also quotes several successful cases of draining basic cavities, probably resulting from pneumonic abscess. The conclusions drawn by Mr. Godlee are that bronchiectatic cavities when single (rare) will be cured by operation, when multiple (common) they offer but small chance of relief by our present surgical methods. An attempt, however, may be made to open the main cavity, if such can be found, but only if the pleura be adherent. Tuberculous cavities should only be opened in cases where the cough is harassing and the cavity single. Sonnenburg[7] describes operations performed on tuberculous cavities, combining this treatment with injections of tuberculin. He obtained fairly satisfactory results from the operation enabling the diseased tissues to be thrown off when affected by the tuberculin reaction, and a granulating cavity left. But he considers that the disease should be local and not chronic and stationary, as such cases are better left alone. Five cases are reported, three of which

Digitized by Google

were nearly well at the time of the lecture; but this was soon after the operation, and it seems difficult to believe that cases can be found where the tuberculosis is so strictly localised that a single operation would reach all the foci. Obviously the later history of these cases is wanted before a judgment can be formed on this method of treatment.

Admitting the desirability of surgical treatment in such cases as may be suitable, as I think all the evidence fairly justifies us in doing, there then remain certain points which have to be considered before coming to a conclusion on the matter. I will now enumerate them. Determination of (1) the existence of a cavity, or whether the symptoms and signs are due to pleural effusion or pneumonia; (2) the locality of the cavity or cavities; (3) the number of cavities and their depth, and the presence or absence of general bronchial dilatation; (4) nature of the cavity, whether tuberculous or bronchiectatic; (5) whether the cavity be in the lung or the symptoms be due to an empyema which has burst into the lung; (6) the presence or absence of a foreign body; and (7) the existence of adhesions. There are also certain more surgical points to be considered—namely, the best position of the opening for drainage, and in the case of apex cavities especially, whether it is possible to establish by operation better drainage than the natural drainage into the main bronchus which already exists. This natural drainage is, however, often not so good as one might expect from the relative position of the cavity and the bronchus. It will not, perhaps, be out of place to emphasise here the importance of not turning the patient over on to the sound side during operation and after anæsthetising, on account of the very real danger of the flow of pus from the affected side into the bronchi of the sound side. If this should take place, death, either from immediate suffocation or from infective pneumonia occurring during the next few days, is an almost certain result. The determination of the points mentioned above must be left to the acumen of those concerned with the case, but if a mistake is made in diagnosis and consequent treatment they have at least the satisfaction of knowing that they are in very good company, and that similar mistakes have been made, and probably will continue to be made, by even the most skilful practitioners of the healing art.

Medical Societies.

HARVEIAN SOCIETY OF LONDON.

Exhibition of Specimens.—So-called Vitiligo.—Some Cases of Syphilis in Children.—Psychroæsthesia.—A Case of Cretinism.—Left Hemianæsthesia with Paralysis of the Left Side of the Palate.—Chronic Rheumatoid Arthritis.

A MEETING of this society was held on May 21st, Dr. GOW being in the chair.

Dr. TRAVERS SMITH showed for Dr. Macevoy a man aged fifty-seven years whose Skin had lately become generally Pigmented, the parts most deeply pigmented being the face, the shoulders and backs of the arms, the external aspect of the legs, a narrow line running over the spine, and a broad belt spreading from over the scapulæ to the front of the thorax and passing underneath the axillæ, where, by contrast, the skin appeared quite pale. The darker areas, with the exception of the thin line over the spine, were more or less thickly studded over with circular or oval white patches, varying in size from that of a hemp-seed to that of a split-pea. On the legs most of these spots were distinctly below the level of the surrounding dark skin and were anæsthetic. The man complained that for the last six months his appetite had been flagging and that his skin had been irritable. He denied having had syphilis or small-pox, or, indeed, any eruption, but said that he heard that when a child he had had the "cow-pox."—Dr. T. D. SAVILL expressed the opinion that the case presented the concluding stage of prurigo, by which he meant a disease attended by severe itching accompanied by small papules and erythematous blotches. Such cases were frequently followed by considerable pigmentation around the seats of the original skin lesions, and the diagnosis was in this case supported by the history and the irritation from which the patient still suffered, which were absent in vitiligo. The position across the shoulders and its characters here favoured the idea that the prurigo in this instance had been originally initiated by pediculi.—Mr. JACKSON CLARKE observed that the lesions in this case were not scars, but due to pigment atrophy as in leucoderma or vitiligo. In several particulars the case differed from average cases of leucoderma. In the first place the lesions were smaller and tended to run in streaks; then the patient was much older than was usual at the commencement of the disease, and then again the affection was attended with marked pruritus, which was not the rule.

Mr. JACKSON CLARKE showed three cases of Syphilis in Children. The first patient, a little girl aged three years, had probably acquired the disease after birth, seeing that the mother was treated for a hard sore when the child was three months old, and that when she first came for treatment, at the age of twelve months, she had a general superficial eruption. She had done well on mercury inunction. The second case was that of a healthy-looking girl aged twelve years. Three years ago she had small gummata of the tongue. These ulcerated, and had left fissures and a superficial glossitis. There were typical Hutchinsonian teeth. When first seen the child was almost blind from interstitial keratitis, though at the present time the corneæ had a normal appearance and the patient could see well. She had been kept steadily on iodide. The third case was that of a baby aged ten months, who had been under treatment for three weeks. When first seen she was extremely asthenic and anæmic and there were mucous tubercles at the anus. There was no enlargement of the liver and spleen. Half a drachm of mercury ointment had been rubbed in over the lower part of the abdomen every night and she had gained greatly in strength.

Mr. HUBERT C. PHILLIPS showed a girl twenty-five years of age suffering from Cretinism. The patient was in good health until she was six, when she moved from Kent to London. It was a typical case. The weight and measurements had much diminished since the commencement of treatment by thyroid tabloids, of which she is now taking fifteen grains a day. Coarseness of the skin and hair is much less marked and strength is increased, the only objectionable symptom during treatment being cephalalgia. The patient is 3 ft. 10 in. in height.

Dr. LEONARD GUTHRIE showed a man aged fifty-two years suffering from Psychroæsthesia (Silvio's). The symptoms were of four years' duration and dated from the occurrence of a loose cartilage in the right knee-joint. They consisted chiefly of constant subjective sensations of extreme and painful cold affecting the whole of the right lower extremity at first, but recently extending to the right arm and left leg to a less degree. The right thigh and leg were somewhat wasted. There was no local tenderness or anæsthesia over the course of the nerves. The electrical reactions were normal, but he showed a remarkable tolerance to strong faradaic currents. Tactile sensations were perfect and also appreciation of heat and cold. The application of heat relieved whilst that of cold intensified the symptoms. There was no actual loss of temperature in the limb and no œdema. The knee-jerks were normal and muscular sense was perfect. He regarded the case as possibly one of early syringomyelia.—Dr. SAVILL thought the case was one of extreme interest and that its features had been most lucidly brought before the society. He agreed with the diagnosis of syringomyelia. Although the symptoms of this disease usually begin in the arms, he had seen a case which had started and predominated, as this one had done, in the lower extremities. The patient was a female aged twenty-nine years, who was admitted under his care into the Paddington Infirmary for paraplegia. The symptoms had started with a numbness and weakness of the feet, followed later by numbness and weakness of the hands. The paresis always predominated in the legs, though the patient could walk a few steps on admission. A few weeks after admission she suddenly fell back in bed and died. At the necropsy the central canal of the spinal cord was found to be dilated from end to end and surrounded in the upper half by a small-celled gliomatous new growth, which by its extension into the medulla had produced sudden death.—Dr. CAGNEY congratulated Dr. Guthrie on the very admirable summary of clinical facts he had given the society. The inference which Dr. Guthrie based upon these facts—viz., the diagnosis of early syringomyelia—was, after all, but matter for speculation, since the early symptoms of that disease, he submitted, had not been adequately observed. It was equally true that the interesting case before the

Digitized by Google

society did not closely conform to any clinical type at present recognised in text-books, but was doubtless one of a very large class with which riper experience would make us familiar. He was not himself disposed to assign a special cause to the symptoms. He pointed out that the wasting paralysis was approximately hemiplegic in character. Extensive, albeit unusual, sensory change was a combination suggestive of cerebral disturbance. He did not suppose that in such a case any change would be found post mortem.

Dr. LEONARD GUTHRIE also showed a woman aged twenty-eight years suffering from Hemianæsthesia and Hemianalgesia of the Left Side of the Head, Face, Neck, and Chest to the level of the third rib, and of the whole of the left upper extremity. She had also double rotatory nystagmus, with marked restriction of fields of vision, the left being most affected. These symptoms were of about three months' duration. Within the past month she had suddenly developed paralysis of the left side of the palate with regurgitation of fluids through the nostril and markedly nasal voice. There was no history of sore-throat, no other motor paralysis, and the knee-jerks were normal. Painless bullæ had appeared from time to time on the fingers of the anæsthetic hand. The symptoms were regarded as functional, but he thought that they might be forerunners of disseminated sclerosis.

Dr. KNOWSLEY SIBLEY showed two cases of Rheumatoid Arthritis successfully treated by the hot-air method. The first, a woman sixty-six years of age, came under his care at the North-West London Hospital in 1892, having previously been under treatment at another hospital. At this time she had considerable enlargement of all the fingers of both hands. These were quite fixed and very painful. The movements of the wrists were also very limited; so also was the right elbow. The knees and shoulders were also enlarged and painful. The patient attended for many months, and although a large number of drugs and remedies were tried she gradually became worse and had to give up her occupation. Then she was unable to dress and finally unable to feed herself and was becoming more hopeless every day. At this time, Aug. 1st, 1894, one of the Tallerman-Sheffield hot-air cylinders was brought to the hospital and this new treatment was prescribed. After the first application the pain was considerably relieved and the joints showed some improvement. After the fourth application the patient, who had been unable to follow her business for many months, was again able to use her needle. After the eighth application with the exception of the right index finger all the others could be flexed without much difficulty. On Aug. 24th, after the ninth operation, the patient reported she had resumed her occupation and she was able to walk up and down stairs without pain. The patient continued under this treatment till Sept. 13th, having then had twenty baths, when she considered herself practically cured, but as the apparatus was still at the hospital she had an occasional bath up to the end of October, 1894. From that date to November, 1895, she continued at her work and with the exception of minor ailments suffered no inconvenience from her former trouble. At this time she again complained of pain and stiffness in the right hand, so three more baths were prescribed; she again rapidly improved, and from that time to the present has continued much as she now is and has not relapsed. The other case was a woman aged sixty-nine years. For some years her hands had been painful and the joints enlarged. She first came under Dr. Sibley's care at the hospital on April 22nd, 1896. Her knees and ankles were somewhat stiff and painful, but the hands were chiefly affected; all the finger-joints were much enlarged; she also suffered much from bronchitis and asthma. This patient had now had fifteen baths, with the result that her knees and ankles were much less painful and her hands much less swollen; so, also, her cough and general nervous condition had greatly improved. Dr. Sibley explained that the treatment consisted in placing one limb, usually the most affected one, in a cylinder heated to about 150° F., and this temperature was gradually increased up to about 240°. The limb was allowed to remain in for about forty minutes. During this time the patient usually perspired freely from the limb, and, in fact, from the whole body. The temperature as taken in the mouth rises one or two degrees, and the frequency of the pulse is also increased. About a quarter of an hour after the limb is removed the temperature returns to what it was before the treatment. The pain in the affected and other parts was greatly relieved, and the patient experienced a considerable feeling of relief generally; especially it was noticed that the bronchitic condition, which so often accompanies this affection, was also much benefited.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Notes on Ovariotomy.

A MEETING of this section was held on **May 1st**, Sir W. THORNLEY STOKER, President, being in the chair.

Sir WILLIAM STOKES read a paper on Ovariotomy based on the results of the last twelve cases he had operated on, ten of which were brought to a successful issue. After pointing out that in the modern evolution of abdominal surgery ovariotomy stands out in boldest relief and referring to the early cases of Clay, Spencer Wells, and Baker Brown, he described the treatment preparatory to operation and quoted with approval the views of Professor Ashton of Philadelphia on this subject. He then discussed several points in connexion with the *technique* of the operation, such as the question of a free or a limited incision, the mode of dealing with adhesions and with the pedicle, the variety of ways in which the ligature may be employed and in which sutures may be inserted, and, lastly, the rules that should be observed in the subsequent treatment. He concluded by remarking that the operation ought not to be regarded as belonging exclusively to the limited province of the specialist, but might be undertaken with confidence in the great majority of instances in a general surgical hospital.

Mr. TWEEDY did not think that general surgeons should perform the operation of ovariotomy. Was the general surgeon prepared to operate on a fibro-myoma in which there might be extensive adhesions to the intestine, bladder, and ureter? Was he aseptic enough? A general surgeon meets every day with septic cases and has his hands bathed in pus. As regards the operation for ovarian tumour there was generally no difficulty in it when once it was diagnosed. The only way to diagnose an ovarian tumour was to feel the pedicle and the round ligament. The person who diagnosed the case should operate on it. The necessary asepsis could only be obtained in a room wholly set aside for abdominal surgery, and not in an ordinary operating theatre.

Mr. WILLIAM THOMSON said that Sir William Stokes had rightly claimed that these cases should be operated upon by the general surgeons. Mr. Tweedy's claim was for the gynæcologist, but when it came to a question of septic hands the gynæcologist was at no advantage in that respect after his morning's examination of his cases. If a general surgeon was unfit to open a serous cavity because of the state of his hands, then he ought not to operate at all or touch a wound; but, in spite of this supposed inability to have aseptic hands, septicæmia had been practically banished from general hospitals. Mr. Tweedy claimed that the case ought to belong to the person who diagnosed it—meaning the gynæcologist. But this assumed that no one else could diagnose an ovarian tumour and that a gynæcologist was necessarily able to operate. This claim was an impossible one. The gynæcologists had been taught by the general surgeon, to whom were due the splendid developments in abdominal surgery.

Dr. WINIFRED DICKSON said that a gynæcologist did not meet with much pus because the general rule was that the patient was douched before being examined. The vagina did not generally contain streptococci or staphylococci, and the gonococcus was not particularly dangerous in the peritoneum. If a case was suspected to be one of cancer it was not examined on the day of an operation. As a general rule gynæcologists operated early in the morning before going round the hospital. She thought nobody used Spencer Wells' trocar now. One point about the after-treatment not mentioned by Sir William Stokes was that the sooner purgatives were begun the more quickly the patient seemed to recover. A great many operators gave a purge twelve hours after the operation.

Mr. LENTAIGNE said that in cases of laparotomy the shock could be lessened by avoiding injury to the peritoneum by a foreign fluid. He now always douched and irrigated with sterile normal saline solution. In suturing the wound he first sutured the peritoneum and then the layers of the abdominal wall with silk, and, lastly, the skin with catgut. He then sealed up the wound with celloidin and used no

Digitized by Google

ressing except to prevent it from being rubbed by the edclothes. The wound could be seen through the transarent celloidin. The celloidin was a great improvement in he treatment of strictly aseptic wounds. He thought it ıade no matter whether a man was a general surgeon or a ynæcologist; if he was a good surgeon he should do ovariotomy all right. The best method of rendering the hands septic was to use oxalic acid. If an operator opened the ıtestine it might easily be as bad as if he had touched some ıs, still he could make his hands clean and finish the peration. He could not altogether agree with Dr. Dickson's inion that the gonococcus is not dangerous.

Sir WILLIAM STOKES, replying, said that Mr. Tweedy tated that unless the pedicle could be felt an ovarian tumour ould not be diagnosed. A considerable number of ovarian umours, however, had no pedicle at all.

Reviews and Notices of Books.

Naturwissenschaftliche Einführung in die Bakteriologie. Von Dr. FERDINAND HUEPPE, Professor der Hygiene an der Deutschen Universität zu Prag. Mit 28 Holzschnitten im Texte. Wiesbaden: C. W. Kreidel's Verlag. (*Scientific Introduction to Bacteriology.* By Dr. FERDINAND HUEPPE, Professor of Hygiene at the German University, Prague With 28 Woodcuts in the Text. Wiesbaden: C. W. Kreidel.) 1896.

DURING the last few years the numerous text-books on ıacteriological technique that have been placed on the ıarket have rendered it impossible for the student to protest hat he has no opportunity of gaining a book knowledge ıf bacteriology. Unfortunately, however, a book knowledge s not all that is required, nor is it absolutely necessary that ı great amount of thought should be expended either in the ;ompilation or in the working through of such books. We ıave now before us, however, a scientific introduction to ıacteriology by Professor Ferdinand Hueppe, in which that ıuthor is found at his best. Those who have already followed Professor Hueppe through his "Methods" and through his 'Forms of Bacteria" will be quite prepared to find here philosophical treatment of bacteriology such as has eldom been attempted; in place of a mere repetition of ıethods and enumeration of species Professor Hueppe has rappled with the fundamental questions concerned and ıas in clear language given a cogent, philosophical, and cientific account of bacteria and their relation to the processes with which they are said to be associated.

In the first chapter the author deals with the forms nd structure of bacteria, and the description given ı certainly the best that has yet appeared, as, although ; is extremely concise, it contains a *résumé* of the est work that has yet been done on this subject, ütschli's and Alfred Fischer's work on the structure f bacteria receiving special attention. The chapter n the Vital Manifestations and Relations of Bacteria ı in many ways extremely suggestive, especially that ortion relating to their nutrition and the formation f their products. A short description of the Organisms pecially Associated with Specific Infective Diseases followed by a chapter on the Causes of Disease, ·eated historically up to the point at which infection and ontagion came to be recognised as due to the action of ıcteria. The latter part of the book deals with the ost interesting questions of immunity, vaccination, pro·ctive inoculation, and curative inoculation; in connexion ith the latter the production and use of antitoxins are ıniidered and the antitoxic and bactericidal bodies of ıe blood. The question of the Specificity of the Action f Serum in Curing Disease is carefully gone into and we ıve in this chapter one of the most interesting that has ɜt been written on this subject. It is pointed out that even the normal serum of healthy warm-blooded animals has an antitoxic effect on specific poisons; the blood of healthy persons in many cases paralyses or antagonises the poisons of diphtheria, typhoid fever, and cholera, although it appears to exert no effect upon tetanus and snake poisons and abrine. It has been objected, however, that in the case of diphtheria, at any rate, the patients may have undergone a slight attack of diphtheria resulting in the formation of antitoxin in the blood; this, however, can scarcely hold in the case of the other diseases. Specific antitoxins produced in the blood act *in vitro* upon certain poisons different from those by which they have been produced; these, however, do not act and inter-act with one another in any very regular manner; for example, anti-venine antagonises the poisonous action of abrine, but not that of diphtheria, tetanus, or ricine; abrine antitoxin exerts its action against snake poison, diphtheria, and ricine, but not against tetanus toxine; tetanus toxine, which is active against venine, has no effect on ricine and abrine; anti-rabic serum exerts an influence on venine, but none on diphtheria or the poisons of tetanus, ricine, or abrine, whilst streptococcus serum, which certainly appears to exert some effect against snake poison, is inactive against all the others; cholera serum antagonises snake poison, but has no effect upon any of the others, whilst diphtheria antitoxin is inactive against venine, the poison of tetanus, ricine, and abrine; the antitoxic serum of "Rothlauf" and typhoid fever are also inactive against the whole of these toxines. Many of the antitoxic serums exert a similar active effect even when the mixture takes place in the body and not in the test tube. Some, however, which act when the mixture is made *in vitro* have no effect when the two substances are introduced separately into the body, and others again which do not antagonise one another *in vitro* still set up a protective action when injected into a living body, an example of this being given in the case of anti-rabic serum when prepared in the rabbit. This serum does not protect against rabies in the dog, but it has the peculiar property of immunising the animal against a dose of cobra poison.

These actions and inter-actions are exceedingly interesting and may be studied with great advantage. Professor Hueppe concludes as the outcome of all this that the specificity of the action of "anti-körper" is not necessary in order to produce an antitoxic action. However, we must refer our readers to the original for further information on this subject, as our space is too limited to allow of further excerpts being made from this interesting chapter.

Chapters on the prevention of disease and the history of bacteriology, though condensed, are exceedingly interesting, and the book as a whole is well worth a most careful reading by every student of bacteriology. It is the work of a master of the subject, who is not only a scientific man in the sense of being an observer, but also in the sense of having a truly philosophic mind.

The Diseases and Deformities of the Fœtus: an Attempt Towards a System of Antenatal Pathology. By J. W. BALLANTYNE, M.D., F.R.C.P. Edin., F.R.S. Edin., Lecturer on Midwifery and Gynæcology and on Diseases of Infancy and Childhood, School of Medicine, Edinburgh. With Plates. Vol. II.: *Congenital Diseases of the Subcutaneous Tissues and Skin.* Edinburgh: Oliver and Boyd, Tweeddale-court. London: Simpkin, Marshall, and Co. 1895

THIS the second instalment of the author's work on "An Attempt Towards a System of Antenatal Pathology" has been delayed in its appearance by unavoidable causes. The author appears to have found his task of greater magnitude than was originally anticipated. He has had to choose between undertaking to embody a consideration of all the

Digitized by Google

remaining maladies of the fœtus within the original limits he had prescribed for himself and discussing all the divisions of the subject in as much detail as in the first volume. He has decided to choose the more arduous alternative, and we think with good reason, for few will differ from him in his opinion that it is better to discuss fully part of a subject than to present the whole of it imperfectly. The present volume deals with the Congenital Diseases of the Subcutaneous Tissue and Skin. The author has evidently devoted to the portion of the subject considered in the volume before us the same laborious industry which distinguished the first instalment of his work. The historical notes must have involved considerable research. It is interesting to observe that sclerema neonatorum has no written history prior to the commencement of the eighteenth century, though, perhaps, we can hardly agree with the author in considering the fact surprising on the ground that it is impossible to doubt its occurrence in earlier times. Modern medical literature, surely, affords almost innumerable instances of diseases that have only been recognised comparatively recently, though as regards many or most of them we may be sure of their having existed in ancient times. The book is illustrated by several excellent plates and there is a copious list of the authorities consulted.

A Pictorial Atlas of Skin Diseases and Syphilitic Affections, from Models in the Museum of the St. Louis Hospital, Paris. London: The Rebman Publishing Company, Limited, 11, Adam-street, Strand.

THE reproductions made for this Atlas are photo-lithochromes, and there are also explanatory woodcuts and text by Besnier, Fournier, Tenneson, Hallopeau, Du Castel, members of the staff of the hospital, with the coöperation of Feulard, the curator of the museum, and Jacquet the secretary. These names are a guarantee of the judgment with which the models for reproduction will be selected and of the interest of the descriptive letterpress. The translation is edited by Dr. Pringle, who points out and explains the differences between English and French nomenclature and gives references to English text-books and monographs.

Those who have visited the museum of the Hôpital de Saint Louis are aware that it possesses a unique series of wax models of diseases of the skin beautifully executed by Baretta and the publication of this Atlas renders this museum to a large extent accessible to all the world. The process of reproduction by photo-lithochrome is necessarily faithful as to the outline, while the colouring is also good on the whole, but the result is less pleasing than chromo-lithographs from drawings of the living subject, as the wax model has necessarily a corpse-like appearance and the artistic accessories are limited to the frill of white cloth round the model. The actual area of disease represented, though of life-size as far as it goes, is small—nine and a half by seven and a half inches—just sufficient to take in the face, and the representation of the characters of the lesion rather than the distribution is therefore the chief aim. If, however, an actual case is compared with a plate a very little imagination will compensate for these slight drawbacks, and recognition of the nature of the eruption will rarely be hindered thereby.

Each part, of which the price is 10*s.* 6*d.*, contains four coloured plates and a liberal allowance of woodcuts in the text, and the enumeration of the subjects of the plates in the three parts now before us will give the best idea of the scope of the Atlas, although the number of parts which the complete Atlas will contain is not stated. Part I. comprises Lupus Vulgaris of the Face; Dermatitis Herpetiformis on the Wrist and Hand (an excellent plate); Chancre of the Vulva; and Purpura Hæmorrhagica of the Thigh. The contents of Part II. are Lupus Erythematosus of the Face; Hypertrophic Rosacea (interesting from its imi tion of the leonine appearance of leprosy); Circinate Pap squamous Syphilides on a profile; and Xanthoma Planum Tuberosum (two figures representing the orbit and palr Part III. represents Four Syphilitic Tongues; Dermati Herpetiformis in Concentric Circles on a Portion of t Trunk; Syphilitic Gummata of the Thigh; and Disseminat Epithelioma of the Face of Sebaceous Origin in Two pro Figures. All of them convey an excellent idea of t disease represented.

Diagnostique et Traitement des Tumeurs de l'Abdomen et Bassin. Par J. PÉAN, Membre de l'Institut de Médecin Chirurgien des Hôpitaux. Tome troisième, avec Z Figures intercalées dans le Texte. (*Diagnosis and Tre ment of Tumours of the Abdomen and Pelvis.* By J. PÉA Member of the Institute of Medicine, Surgeon at t Hospitals. Third Volume, with 228 Figures in the Text Paris: G. Masson, Éditeur, Libraire de l'Académie d Médecine. 1895.

IN this volume, which consists of over 1000 pages, t author deals with the diagnosis and treatment of tumours the uterus, of the Fallopian tubes, of the ovaries, of t round and broad ligaments, and of the pelvic peritoneum a cellular tissue. He has evidently used the word "tumo in a broad sense, so as to include every form of swellin whether produced by an actual growth, innocent o malignant, or by inflammatory processes. Thus, while w should, from the title of the work, naturally expe to find an account of fibroid tumours of the uterus and cancer of the uterus, we are, perhaps, not quite prepared t find an account of chronic metritis and of syphilitic affe tions of the cervix. There is an interesting table of thirty four cases of extirpation of the uterus for cancer, from which it appears that four deaths only resulted from the operation but as regards recurrence, the cases, with one or two excep tions, had not been watched for a sufficiently long period t enable any conclusion to be reached as to the remote effects of the operation. The volume before us contains a great deal of information that cannot fail to prove valuable t those interested in the subjects of which it treats.

JOURNALS AND REVIEWS.

Science Progress.—The May number of this monthly review contains some very interesting as well as opportune papers. The first is by Dr. Frankland on The Past, Present, and Future Water-supply of London, being the discourse delivered by him at the Royal Institution on Feb. 21st. Dr. Frankland, as is well known, takes a very optimistic view of the future of London's water-supply. He concludes the present article in the following glowing terms: "Nevertheless, by means of storage, by utilising springs, by sinking deep wells, and by such comparatively simple means, we have, in my opinion, every reason to congratulate ourselves that for half a century at least we have at our doors, so to speak, an ample supply of water which for palatability, wholesomeness, and general excellence will not be surpassed by any supply in the world." In a paper on Atomic Weights by Alexander Scott, M.A., it is pleasant to learn "that that type of worker of whom we regard Stas as the chief is not yet extinct. In spite of the prevailing view that one must publish as many papers as possible in the least possible time before one can be said to engage in 'original research.'" Part 2 of this Stellar Theory is continued by A. G. Tansley, B.A., and Part 2 of The Present Position of the Cell Theory by G. C. Bourne, M.A. The volume concludes with a short paper on Ferns, Aposporous and Apogamous, by C. T. Druery, F.L.S.

Hospital Sunday Hymn. By the Rev. W. SMALE, M.A., Vicar of St. Philip's, Kensington. The music by WARD

Digitized by Google

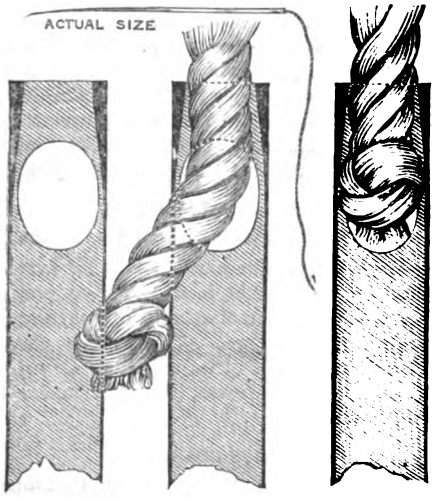
DENNIS. London: Novello, Ewer, and Co., Berners-street. Price 2*d*.—To those in need of a special hymn for the approaching Hospital Sunday services we can commend this. The music and words are well suited to each other and their theme.

New Inventions.

SURGICAL NEEDLE DESIGNED TO HOLD A SINGLE THREAD.

THE accompanying illustration shows a diagram of a section of a round needle, characterised by a central conical canal having its apex directed upwards, situated in the head beyond the eye. Fig. 1 shows the conical canal, Fig. 2 the knotted silk in process of threading, and Fig. 3 the knot *in situ*. To thread the needle. (*a*) Tie a simple knot in the silk as tightly as possible and cut off the loose end beyond the knot *flush with the knot*. (*b*) Thread from the eye towards the head. (*c*) Pull the silk until the knot is concealed within the central canal. The knot becomes wedged in the canal and cannot slip either up or down; it can, however, be easily pushed through the eye transversely with the point of a needle. There is no difficulty in threading with silk of a suitable size. The design has been carried out with great skill by Messrs. Lawson and Sons of Old Steyne, Brighton. The sizes[1] made are

FIG. 1. FIG. 2. FIG. 3.



from Size 6 of an ordinary sewing needle. This sized needle can take either fine silk or a horsehair; in the latter case the hair should be wetted and the thicker end passed through a flame to produce an olivary bead, which answers all the purposes of a knot. My object has been to produce a round needle especially adapted for peritoneal and cosmetic surgery. The advantages claimed are: 1. A single instead of a double thread. 2. The needle cannot slip off the thread. 3. Diminution of bulk at the eye, thereby producing the minimum of disturbance of the parts during the passage of the loaded needle through the serous coat or other delicate tissue. After use the needles should be dipped in hot water and put away threaded with dry silk.

W. D. CALVERT, M.R.C.S. Eng., L.R.C.P. Lond.
Brighton.

A SOUND-POST STETHOSCOPE.

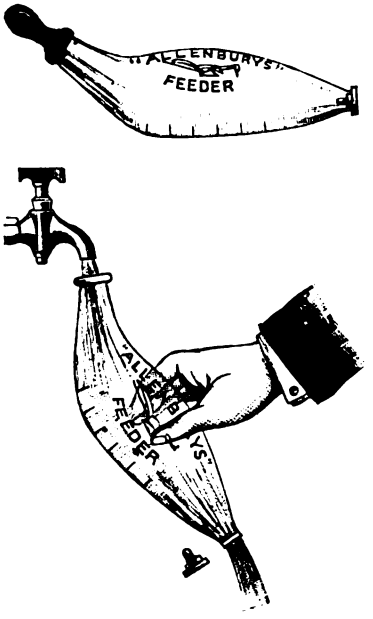
MESSRS. ARNOLD AND SONS of West Smithfield have made for me a stethoscope which I think conveys sounds from the patient's chest to the physician's ear more distinctly than the ordinary tube. This stethoscope is made on the principle of the sound-post which unites the belly and back of the violin represented by discs of wood or other material placed near the ends of a stethoscope tube; these vibrate and so convey

the pulsations which are ordinarily conveyed by the column of air. This stethoscope can be made at a price little exceeding that of the ordinary ones.

Fellows-road, N.W. H. FLY SMITH, M.B. Oxon.

THE "ALLENBURYS" FEEDING-BOTTLE FOR INFANTS.

MESSRS. ALLEN AND HANBURYS, Limited, of Plough-court, Lombard-street, E.C., and Vere-street, Cavendish-square, W., have recently introduced an improved form of infants' feeding-bottle, which embodies several important advantages. The object of the designers has been to provide a bottle which shall admit of being easily and effectually cleansed in every part, and thereby freed from any suspicion that souring of the milk and digestive troubles on the part of the infant have been due to minute portions of milk inadvertently retained in some crevice. Perfect cleanliness was almost unattainable with the narrow glass tube, indiarubber tube, bone shield and teat of the old-fashioned bottle, but the present model, being open at both ends, can be easily washed at an ordinary water tap and thoroughly wiped or brushed inside. When in use one of the ends of the bottle carries the nipple, which is of smooth indiarubber and can be readily turned inside out for better cleaning. The other end of the bottle is closed by an indiarubber stopper containing a valve, which admits of air being sucked in behind the food as fast as the infant sucks the food out, so that the infant is not forced to strain in sucking and the teat has no tendency to collapse through the external pressure of the air. This bottle is said to be an improvement on one which is very widely used throughout the United States and also in France.



THE YORKSHIRE BRANCH OF THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The annual meeting of this branch was held on June 2nd at Leeds, when Mr. W. H. F. Ramsden presided. The report showed that last year there were sixty-five members of the branch, of whom forty-eight were members of the parent society. During the session twenty members and two associates were elected, making a total membership of eighty-seven, which, however, is still but an inadequate representation of the health officers of so large an area as Yorkshire. In the evening a complimentary dinner was given to Dr. Whitelegge, late medical officer of the West Riding District Council, who has recently been appointed to the office of Her Majesty's Chief Inspector of Factories.

[1] This figure of the actual size in printing comes out much too bulky, being in reality about half the size.

Analytical Records
FROM
THE LANCET LABORATORY.

TABLOIDS OF (1) EFFERVESCENT BITARTRATE OF LITHIA; (2) EFFERVESCENT CITRATE OF LITHIA; (3) PANCREAS SUBSTANCE; AND (4) MAGNESIUM SULPHITE.

(BURROUGHS, WELLCOME, AND CO., SNOW HILL-BUILDINGS, E.C.)

IT is evident from the important additions that are made from time to time that new remedies are not meant to be excluded from the "tabloid" list. The above are examples of recent useful additions. The first (bitartrate of lithia) have been prepared with the view of providing a convenient and reliable means of administering the bitartrate which it is suggested increases the alkalinity of the blood, eliminating uric acid. The fate of bitartrates in the organism or other organic salts, as citrates and malates, is similar, of course, to that when these salts are burnt, a residue of carbonate of the alkaline metal is obtained. Effervescent lithia citrate tabloids are prepared with a similar object in view. They are agreeably effervescing, and it is suggested also that they may prove useful when dissolved in an ounce of water as an external application to gouty swellings. Pancreas substance tabloids represent, it is stated, the whole substance of the gland in a pure reliable form, and contain the active principles in an unchanged state. They are keratin-coated to ensure the passage of the pancreas substance through the stomach unchanged to the alkaline digestive tract. Pancreas substance, as is well known, has been administered with marked benefit in diabetes mellitus, an effect which is "produced by the artificial supply to the blood of a principle (produced by the epithelioid tissue of the pancreas) which profoundly modifies the carbohydrate metabolism of the tissues." Magnesium sulphite was suggested some time ago as of service in disinfecting and destroying the membrane in diphtheria. In the form of tabloids it may conveniently be sucked, the salt gradually decomposing, giving rise to free sulphurous acid (which is very obvious in the mouth) and probably hydrated magnesic oxide.

COFFEE AND CHICORY ESSENCE.

(BROMLEY AND CO., BLOOMSBURY WORKS, LEEDS.)

This is avowedly a mixed extract, its solution in hot water possessing a good rich aroma and "body." Distinct evidence of its genuineness and value was afforded in the fact that on suitable treatment crystals of caffeine, the important stimulating principle of coffee, were extracted from it. It is free from objectionable admixtures.

PEARL OLD IRISH WHISKY.

(MARGRAVE BROTHERS, BRIDGE-STREET, LLANELLY.)

The general characters of this manifestly pure spirit give evidence of skill and experience in blending. It possesses the taste and aroma peculiar to Irish whisky, and presents on analysis the composition of a well-matured product. The results were as follows: alcohol, by weight 39·80 per cent., by volume 49·13 per cent., equal to proof spirit 82·59 per cent.; extractives, 0·37 per cent.; mineral matter, 0·005 per cent.; acidity reckoned as acetic acid, 0·024 per cent. It is a wholesome spirit and practically free from acidity.

MEDICINAL TOKAY WINES.

(ERN. STEIN, AGENCY, W. BEST AND SONS, 22, HENRIETTA-STREET, CAVENDISH-SQUARE.)

The well-known Tokay wines of Hungary have long been accredited with peculiar properties. They do not appear to disturb the digestive functions as is the case with wines containing a marked amount of astringent substances, while their very distinctive flavour, thin, sweet, and delicately aromatic, is an attractive feature. According to our analysis and examination this is true of the specimens before us, which are undoubtedly genuine and pure. The following results were obtained:—Medicinal Tokay Sweet (2*s.* 9*d.*): extractives, 18·94 per cent.; mineral matter, 0·32 per cent.; alcohol, by weight 13·69 per cent., by volume 16·89 per cent., equal 29·60 per cent. proof spirit. Medicinal Tokay Dry (3*s.* 3*d.*): extractives, 16·84 per cent.; mineral matter, 0·24 per cent.; alcohol, by weight 12·92 per cent., by volume 15·96 per cent., equal to proof spirit 27·97 per cent. Medicinal Tokay Sweet, extra fine (4*s.* 6*d.*): extractives, 27·26 per cent.; mineral matter, 0·46 per cent.; alcohol, by weight 12·15 per cent., by volume 15·02 per cent., equal to proof spirit 26·33 per cent. Medicinal Tokay Red, sweet (3*s.*): extractives, 7·78 per cent.; mineral matter, 0·1 per cent.; alcohol, by weight 13·85 per cent., by volume 17·08 per cent., equal to proof spirit 29·92 per cent. They are all excellent types of this peculiar wine, the properties of which render it of especial value in suitable cases.

SAVAR'S COCA WINE.

(EVANS, LESCHER, AND WEBB, 60, BARTHOLOMEW-CLOSE, E.C.)

This is a concentrated and permanent spirituous solution of the leaf of erythroxylon coca, which is useful for the extemporaneous preparation of coca wine. It may be taken in dessert-spoonful quantity in half a wineglassful of water or wine before meals, and after a time in double quantity. Each large bottle is stated to contain the active principles of about 2000 leaves, so that a quarter of an ounce would be the equivalent of twenty-five leaves. The wine is marked by the peculiar leafy flavour of the plant and yields an abundance of cocaine when suitably extracted. It is evidently a reliable and a standard preparation, which enables the practitioner to prescribe with confidence an exact dose of the restorative principles of the plant.

LIEBIG'S MALTED FOOD.

(W. M. BELL, 2, MALVERN-ROAD, WEST KILBURN.)

Treatment both by malting and cooking has evidently been the process by which this food has been prepared. It contains a large proportion of soluble carbohydrates including dextrine and malt sugar. The taste is pleasant, and there can be little doubt of its nutritious as well as of its digestible character. Moreover, it contains an excellent proportion of mineral food.

MAGGI'S CONSOMMÉ.

(COSENZA AND CO., 95 AND 97, WIGMORE-STREET, CAVENDISH-SQUARE.)

Apart from the convenience of the form of this preparation, consisting of concentrated meat essence contained in gelatin tubes enclosed in gelatin capsules, it possesses real nutrient as well as stimulating properties. Alcohol gives an abundant precipitate of peptoniferous matter, whilst the crystalline meat principles are found in solution; albumin also occurs to an important extent and is thrown down on boiling the solution of the contents of the cartridges after the addition of a few drops of acetic acid. Each tube makes three-quarters of a pint of nearly clear broth of good beefy flavour with a *soupçon* of spice and salt, which add to its palatability. The capsules should prove of great service and convenience in the invalid's dietary, whilst affording also an easy means of extemporising a really good *consommé*.

ROYAL BAKING POWDER.

(WRIGHT, CROSSLEY, AND CO., 17, NORTH JOHN-STREET, LIVERPOOL.)

It is sufficient to record that this powder on analysis was found to be free from objectionable ingredients, and especially alum. On moistening a copious evolution of gas was given off. It is therefore a good and wholesome yeast substitute.

THE LANCET.

LONDON: SATURDAY, JUNE 6, 1896.

IN entering to-day upon a second decade of Special Supplements in support of the Metropolitan Hospital Sunday Fund we feel that we may dispense with the language of apology which was appropriate to our earlier issues of this kind. We address ourselves in this chapter to a body of readers wholly outside the circle of those to whom, as a rule, we submit our weekly issues. But it is by this time well understood on the part of our readers, both medical men and laymen, that we make this departure from our custom in the interest of a cause which is the common cause of all alike; in the interest of a great work of charity which, as being directed to the relief of the ravages occasioned by personal accident and by disease, is in a peculiar sense dependent upon medical support, but which, by reason of the magnitude upon which its operations are conducted, goes much beyond the power of any particular class in the community, and demands and receives the support of the great public, including rich and poor, great and small—everybody who can help with a pecuniary contribution or with personal service. We mention personal service in this connexion because, although pecuniary aid is in a special sense the form which charity takes on Hospital Sunday, it would be less than charity if the personal element were wanting which mere pecuniary support can never replace. Of the many thousands who on Sunday next will testify to their interest in hospital work by larger or smaller contributions to the Hospital Sunday Fund collection a very small percentage only will be capable of contributing anything but money to the great work. And yet those whose personal service is one of the wings upon which this great charity supports its flight will by no means be found to hold aloof from the voluntary tax to be then decreed by an unqualified universal suffrage upon Londoners. From the hospital physician to the hospital drudge every class and grade in the ministry of the hospitals will be found represented in the congregations of the metropolis and contributing in proportion to its means to the pecuniary support which constitutes the second wing of medical charity. The blessedness of giving in this most literal sense of the word is a delight for which those whose chief blessedness is in doing will be in no sense backward to compete. But the gifts of money must chiefly come from those who have nothing else to give, and the fact that they are thus shut up to this one form of helping the great work forward should act, and will act as we believe, as a powerful incentive to generosity.

In the statement which we to-day issue—a statement which rests more than some others that we have submitted upon the purely public aspects of the question—we have endeavoured to show in some detail how the existing organisation of the Fund supplies the want of a coördinating and governing body among the voluntary medical charities of the metropolis, and to display the extent, as measured by pecuniary support, to which the individual members of the public interest themselves in this annually recurring function. To many, perhaps to most, of our readers both of these views of the subject will disclose some very striking facts. It will scarcely be less than a revelation that the churches of the metropolis, upon this, the occasion when they make their supreme effort in the cause of philanthropy, cannot secure so much by way of contribution as a farthing a head from Londoners all round. It will be perhaps equally surprising, but in a more agreeable sense, to learn how much is done quietly—so quietly that it may fitly be said to be without observation—to secure the vital objects of economy and efficiency in connexion with hospital administration. At a minimum of cost for official work, with a minimum of trouble and offence to the institutions whose work comes under review, the control of the Council is exerted over practically the whole medical charity of London. Two great hospitals, monuments of the piety of an earlier day, are able to maintain their work without subventions from the Fund, and a few obscure institutions are not able to qualify for a share in its distribution, but these are the most notable exceptions to the rule that through the instrumentality of this great institution the influence of the church is brought to bear upon the work of medical relief with what are, upon the whole, the most beneficent results.

This popular control is not, it must be admitted, wholly without its drawbacks. But nothing is; and the worst that can be said about the spontaneous Hospital Sunday movement is that it has given occasion to a few mistaken people to thrust their views very unpleasantly forward in a singularly unprofitable or even mischievous way. We have ourselves become involved within the past week or two with certain people quite unknown to us who, probably with the best intentions, have sought to turn this collection into an occasion of strife concerning the ethics of physiological experiment. This, like many other questions of morals, is one upon which it is quite possible to be mistaken, and we do not for a moment question the integrity of those persons who, entertaining strong views, assail with unmerited vituperation the leaders of physiological research. To be misunderstood and misrepresented has been the fate of those who have led the van in every work of charity, from the Founder of Christianity downwards through all the ranks of the benefactors of mankind. He would be unworthy of the position of a pioneer in any department of human progress who was not prepared to face misrepresentation at the hands of those who know ill though they mean well, and to encounter the unreasonable hostility of good but uninstructed people. The pathologist who knows what momentous issues in the way of the mitigation of suffering and the saving of life both to men and brutes lie in the successful modification of a bacterium, or the production of a benignant amœboid growth, cannot possibly desist from his work of mercy merely because some of his neighbours, whose good opinion he would gladly enjoy, mistake him for a monster of cruelty. He cannot justify himself to their judgment for the same reason for which the ordinary practitioner could not, if he would, justify to his patient his treatment of a particular disease. Practical experience has taught people gifted with common sense that in order to discuss a

Digitized by Google

medical question with profit a preliminary medical education is necessary, and they act accordingly. They place their personal interests unreservedly in the hands of some medical man in whose knowledge and integrity they have confidence, and they say to him: "Treat us according to your lights; the details we leave to your better judgment." The position of the pathologist is analogous. He occupies himself with the larger interests of classes and populations and species rather than with those of individuals, and therefore his methods differ from the methods of the general practitioner; but in this case, no less than in the simpler case where the individual is alone concerned, whosoever would profitably discuss the mode of procedure must be prepared to submit first of all to the preliminary scientific education. Apart from this condition it must be matter of pure chance whether his conclusions be sound or unsound, for his mind is not accessible to the only relevant arguments.

It is, therefore, the necessity of the case and not pique which makes us refrain from the attempt to vindicate our character against the aspersions which have been cast upon us in connexion with the work of physiological research. That this patient endurance of misrepresentation and obloquy must injure us in the eyes of some among our neighbours we fully recognise; but though we regret the fact, we recognise that such regrets are futile, for it cannot be helped. It is the result of invincible ignorance.

But very different considerations arise when we find that an attempt is being made to make the region of medical charity the battlefield of this polemic. A circular to which we drew attention last week has, by suggesting that the hospitals might be placed in a difficulty, which would soon become intolerable, if a concerted movement were set on foot to make the suppression of physiological research a condition of the churches' contribution to their funds, has placed the matter in a very different light. We quite admit that if any section of the charitable public chooses to press a point with fanatical insistency it can make coöperation impossible, and that the multiplication of such grounds of difference would very speedily dissolve the great organisation which the patient labour of the past one-and-twenty years has so happily built up. That views, mistaken views, strong views, should be entertained does not surprise us; we do not complain that they should be bitterly expressed. All this, though unwelcome, is but wholesome human nature. But when one set of conscientious people denounce another set of people equally conscientious with the unmeasured violence of the circular, and in furtherance of the views they chance to hold would stay the hand stretched out to tend the sick and succour the dying—and this *in order that the cry of the suffering poor may become unendurable—then* our patience gives way. Then it becomes our duty to cry to them "Hands off!" and to denounce them to all honestly charitable folk as people whose misguided conscientiousness is itself of the nature of a vice, since it cloaks and gives respectability to conduct purely mischievous—conduct which would, if it went unchecked and attained its ends, accomplish the most cruel and enormous harm.

But this will not be. In the work of collecting and administering the Hospital Sunday Fund the churches have shown an unprecedented—may we not say an unsuspected—power of sinking points of difference and subordinating to the ends of practical charity all the influences which tend to hamper or to frustrate their coöperation. The results of this most beneficent concert have furnished us with the theme of our Supplement to-day, and we have confidence alike in our fellow workers and our cause—a confidence which forbids us to entertain any misgiving on this point or to doubt that, having once joined hands and forces in such a sacred cause, the churches of the metropolis and those who represent them in this matter will suffer anything to distract their attention from the great body of suffering which it is their special function to relieve, or to paralyse their efforts by fruitless bickerings and unprofitable discussion.

Upon a comparison of the diagrams showing the growth of London during the past five years with the article which appears in another column upon the results of the recent census, it will be seen that the figures adopted in the Hospital Supplement article are not perfectly correct. New London is made to represent a population of 221,000 instead of 199,528, as it should have been. The article in question was written and the blocks were prepared in advance of the publication of the figures, and being partly based on estimates have turned out a little wrong. The error, although considerable enough to demand mention, is not of a magnitude to affect the argument in any way, or even visibly to alter the dimensions of the figure which represents New London in the woodcut.

NEVER perhaps before in the course of history has a more pathetic and awful example of the aphorism *memento homo quia pulvis es* been recorded than in the news received recently from Russia. Amid all the pomp and majesty by which the blend of Orientalism in the Russian character is so marked the young Emperor had been inducted into the full possession of his sovereignty. The Church had declared the Divine blessing upon his head and from all parts of his vast Empire had come elders, heads of tribes, and deputies of all kinds to testify by one act their rejoicing and their willingness to be his men. Everywhere was pleasure, gratitude, and joy. Two days after "all was in the dust," and in place of rejoicing there was mourning.

That even the humblest classes might say that they had had a share in the general distribution of presents and gifts a dole had been arranged for consisting of sausage, cake, sweets, &c., and these were to be distributed on the Khodinsky plain. A row of wooden booths with barriers had been erected and from this centre the distribution was to be made. The crowd began to assemble upon Friday night, and upon Saturday morning one of those uncontrolled and blind impulses by which crowds are sometimes affected if left to themselves came upon the mass of people. They pushed irresistibly forward, and when the foremost ranks were checked by the barriers the hindmost continued their advance, with the result that some two thousand persons were crushed to death. There is no need here to go into the horrors of the scene or the heart-rending incidents which have already been fully reported in the daily press. Suffice it to say that the gloom which

Digitized by Google

the disaster has cast over the land is unparalleled, for such a catastrophe, lamentable at any time, becomes doubly so when we contrast it with the circumstances which in a way led up to it. With whom the responsibility rests is not very clear and probably will never rightly be known. It is always easy to blame, especially after the event, and presumably the authorities were not so much wilfully careless as worn out. A crowd as large as this was—for though the numbers vary in different accounts it obviously was enormous—is almost impossible to control after it has collected. It must be broken up during the process of aggregation and kept moving. Stagnation means pressure and pressure means death. If twenty or thirty different distribution centres had been arranged, and if the crowd had been broken up as it was collecting all would probably have been well.

That a crowd should assemble in such numbers and should become so out of hand for so small a dole as a sausage, a cake, and a tin mug may seem extraordinary, but to anyone who knows the Russian character the course of events will appear plain. The gifts were the gifts of the Czar; the tin mug has his portrait upon it, and the absolute devotion of the Russian peasant to the "Little Father" is a thing that no one who has not seen it could believe. To the peasant the Czar is everything. He is the head of the Empire, the head of the Church, the father, friend, and protector of his people. In every cottage his portrait hangs and is looked upon with almost the same reverence as the sacred "Eikon," and it was this feeling that urged the vast mass to what proved to be the death of many. For the relatives of the dead we grieve; with the officials whose duty it was to control the crowd we deeply commiserate; but especially for the young ruler whose position, responsible and burdensome at all times, has had added to it an additional sorrow by the death struggle on the Khodinsky plain, our sympathies are of the deepest.

THE sixtieth session of the General Medical Council commenced on Tuesday last in the new council chamber. The time of the first day was largely occupied by an address from Mr. T. PRIDGIN TEALE urging his colleagues to consider the present condition of medical examinations. His speech in support of his resolution will be found printed at length at the commencement of this issue, p. 1547. We have so frequently urged that our medical examinations are too numerous and often unjust in their incidence on the candidates that we are pleased to see that the General Medical Council has considered the matter from a practical standpoint. No one is better qualified than Mr. TEALE as a teacher, inspector of examinations, and practical surgeon to urge the importance of this matter. Practically we have to admit that the students who are studying for an entrance into our profession are over-examined, and that many of the examinations are so conducted that they cannot possibly do justice to the individual candidate. The greater the number of examinees the greater is the certainty of such injustice. With a time-limit this injustice is absolutely assured. If examinations are increased in number the injustice becomes more pronounced in a strict ratio to the sub-divisions of the various examinations.

There are only two really substantial reasons for examining a medical student or any other professional student, and these should always be most held in view by the authorities who have charge of his professional education. The first of these is to see that he is sufficiently well acquainted with the subjects of preliminary education to enable him with advantage to pass on to the study of the technical requirements necessary for him to practise the daily work of his profession. The second is, of course, to see that he has learned his work sufficiently well to enable him to practise with benefit to the public. With regard to the first, is the present guarantee in preliminary education a sufficient one? We allow that the standard has been much improved in recent years by the insistence on the passing of the preliminary subjects *en masse* instead of in detail, as was formerly the case; but even now the standard could be raised with advantage. It is at this end that the unfit should be stopped. The student who is bound to extend a five years' education into one of seven, or even more, years should be peremptorily barred. A proper course of education extending over four years is amply sufficient for a well-educated man to become conversant with the theory and practice of medicine, surgery, and midwifery, and, therefore, to take his place in our ranks as a properly qualified medical practitioner. As Mr. TEALE shows, this does not now take place, and even after a five years' curriculum some 30 to 40 per cent. fail to pass. The multiplicity of examinations in different subjects to which every individual student is subjected, and for which, as well as for the preliminary education, the General Medical Council is responsible, is the main reason for their heavy percentage of rejections. It is to this question that Mr. TEALE has devoted his attention, and his speech and his suggestions for decentralisation must have every consideration from the teachers and examiners as well as from the members of the profession in general. In 1861 medical students were rejected at the rate of 12·4 per cent.; in 1892 at a rate of 39·3. Meanwhile, the standard of medical preliminary education has steadily advanced. Do these statistics mean that the present medical student is to the extent of more than one in three inferior in professional knowledge to his predecessors of thirty years ago? Unquestionably not. But what they demonstrate is that the sub-division of examinations has increased more than threefold the chances of his failure at some part of his career. (Is it to be wondered at that with these statistics the main idea of all is to "get through," and to secure this event by "cram, cram, cram"?) The clinical examination of the students is, by most examining boards, the least considered and the least thorough. The plan which Mr. TEALE suggests for the improvement of the present mistaken system is one of *decentralisation*, and we are glad that he has not only attacked existing evils, but has suggested a remedy which seems to us fairly adequate. "We must unload our public examination," says Mr. TEALE. "We must relegate to the schools not only to teach, but to examine and to certify in all secondary subjects, such as elementary biology, materia medica, pharmacy, hygiene, perhaps even

Digitized by Google

chemistry, and certainly forensic medicine. Then let *all the rest* be covered by three public examinations—one in anatomy and physiology, presumably at the end of the second year of professional study; one in pathology and therapeutics at the end of the fourth year, and the clinical examination in medicine and surgery, together with examination in midwifery (truly in midwifery, not in fancy gynæcology) at the end of the fifth year. Surely after that we may see the ten minutes' bell and all it implies abolished. The licensing bodies will be able to afford to examine more thoroughly, less hurriedly, to find out what a student really knows and to re-examine those on the border line of pluck or pass. Then, when plucking examinations are reduced from nine to three and become less matters of chance, there will be some room for calm clinical study, for self-training, for learning something during studentship of that very important and terribly neglected better half of the training of a true medical man, the knowledge and observations of a human being."

We are almost entirely in accord with Mr. TEALE in his recommendation. In our opinion examinations in elementary biology, chemistry, and physics should be left to general and not professional examining bodies. The student should be registered on entering on the study of either of them and be allowed one year out of the five on passing these subjects, which should not be allowed to hinder his purely medical routine. It would be the duty of the General Medical Council to schedule in official manner the examining bodies whose certificates in these subjects would be considered adequate. In the other four years, which should be strictly devoted to a technical curriculum, the student cannot do better than follow Mr. TEALE'S advice, to which we refer him, and the sooner the examination system is altered on the lines of his remarks the better will be the training of the medical student and the greater the advantage of his education to the community.

Annotations.

"Ne quid nimis."

THE COMING ELECTION TO THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

NOTICES, dated June 2nd, have been issued by the Secretary of the Royal College of Surgeons of England that "a meeting of the Fellows of the College will be held at the College, in Lincoln's-inn-fields, on Thursday, the 2nd day of July, *at 1.30 o'clock in the afternoon precisely*, for the election of three Fellows into the Council of the College." Intending candidates are informed that blank forms of the requisite notice from a candidate and of his nomination may be obtained on application to the secretary, and the same must be received by him, duly filled up, within ten days from the date of the circular—i.e., *not later than on Friday, the 12th day of June next*. A voting-paper will be sent by post to each Fellow whose address in the United Kingdom is registered at the College on Monday, the 22nd day of June next, and Fellows will not be required to apply for voting-papers. The vacancies to be filled are created by the retirement of Mr. Bryant, Mr. Cadge, and Mr. Pick on the completion of the full eight years' term of office. Mr. Bryant and Mr. Cadge were first elected in 1880, and have therefore each served for sixteen years or for two full periods of eight years consecutively, both having been re-elected in 1888. Mr. Bryant, who has passed the chair, is the representative of the Council of the College on the General Medical Council of Education and Registration, and will stand again. Mr. Cadge does not intend to do so. Mr. Pick, who is one of the Vice-Presidents, and has only enjoyed one full term of eight years as a Councillor, will naturally offer himself for re-election. We have not yet before us the names of all the other intending candidates, and, therefore, defer further comments till the list is officially complete. It may be noted that as there are no death vacancies this year the number of vacancies is three—the usual number of vacancies by rotation. Next year, in the absence of any death vacancies, the number of vacancies will depend upon the re-election or not of Mr. Christopher Heath as President of the College. Mr. Heath's second term of eight years on the Council expires next year; but if he is re-elected President he will not retire, a clause in the charter expressly providing for this contingency.

"PROTEST AGAINST THE INJUSTICE OF THE MEDICAL AUTHORITIES."

UNDER the above heading we published in our issue of March 21st some remarks reflecting on the action of Dr. J. B. Crozier in issuing a card intimating, amongst other things, that he would see patients whose income was under £2 a week at a certain scale of fees. In our issue of April 4th we published a letter from Dr. Crozier explaining his position. The matter came to the knowledge of the Royal College of Physicians of London, and that body, after due consideration, have informed Dr. Crozier that "they gladly accept his explanation and consider it satisfactory." While we are fully in sympathy with Dr. Crozier's grievance and also agree that a ready money fee, however small, from a poor patient is better than the club or contract system, we still think his method of drawing attention to the matter was a mistaken one. We recognise, however, his *bona fides*, and are glad to see that the Royal College of Physicians of London have accepted Dr. Crozier's view of the matter.

HORSEFLESH AS FOOD.

PRIVATE opinion may be allowed to decide what is agreeable to the palate, but wholesomeness in diet cannot be regulated by the same flexible standard. Certain statistics recently published in connexion with the Belgian trade in horseflesh are interesting as bearing on this subject. From these it appears that about 6000 horses were exported last year from this country as part of the food-supply of the poorer classes in Belgium. Most of these were old and wretched animals and, what is of much greater consequence, a certain proportion were affected with glanders. Such evidence of mismanagement as these facts afford has naturally attracted the attention of the Belgian Government, who have accordingly taken steps for the better supervision of the horse traffic, and especially for the detection of glandered animals. As a preventive makeshift this arrangement is no doubt reasonable and convenient. No one can pretend that it satisfies the conditions necessary to healthy nutrition, for we cannot suppose that it will do more than condemn the carcases of animals which are actually diseased. Until the horse is reduced by the general employment of mechanical motors to the state of a mere lounger like the pastured ox we need not expect that any but maimed or superannuated animals will contribute materially to the food-supply of a poverty-stricken population. Bad at the best will be, for a long time to come, the sinewy meat provided by the horse-butcher. It is clear that under such conditions thorough

Digitized by Google

supervision by capable veterinary officials is alone compatible with public safety. It appears to be taken for granted that all this inferior horseflesh is consumed in Belgium itself. There have been suggestions notwithstanding that this is not the case. In consideration of certain disquieting rumours which have been set afloat in the British press we would suggest as a highly proper and legitimate subject of inquiry for the official supervisors of *abattoirs* the question, How much of this meat, if any, returns to the British Islands, and under what name?

THE DEATH OF SIR GEORGE JOHNSON.

WE deeply regret to announce the death of Sir George Johnson, M.D., F.R.S., Physician Extraordinary to Her Majesty the Queen, which occurred at his residence, 11, Savile-row, on Wednesday afternoon last, June 3rd. The deceased gentlemen, who was in his seventy-eighth year, had been in excellent health up till Monday, but on returning from a drive on that afternoon he had a hemiplegic attack, from which he never recovered. We shall give an extended notice of Sir George Johnson's career in our next issue.

COMPARATIVE PAUPER STATISTICS.

IT is satisfactory to be able to record a continued decline in pauperism, as shown by the monthly comparative pauper returns issued by the Local Government Board. We have before us the return for the month of March, and we find that in all the several divisions of the country there has been a decline in the amount of pauper relief as compared with March of 1895, and that this is true of each week of the month. Certainly it is said that the present year has had freedom from the severe frost prevalent in February of last year and which was of a character to have an influence on the March pauper data as well as those of February. At the same time the figures are encouraging. In London as regards the first week the decline was as much as 22·0 per cent. on the corresponding week of March, 1895, and 15·0 per cent. in the closing week. In England and Wales the rates of decrease in 1896 as compared with 1895 were 9·5 per cent. in the first week, 7·9 per cent. in the second week, 6·3 per cent. in the third week, and 5·7 per cent. in the fourth week. In proportion to population the rate per 1000 in the last week of March this year was lower than in any of the years 1857–95, except the four years 1891-94.

THE LAY REPORTER AT CORONERS' INQUESTS.

OBSCURE and unusual cases are always worth recording in their proper place, but the details of inquests which often find their way into the daily press serve little end but the satisfaction of a morbid craving on the part of the public. Capital is too frequently made out of details which are exceedingly inaccurate, and a very false impression may be created in the mind of the public. In more than one of our evening contemporaries paragraphs appeared last week relating an "extraordinary death" which occurred at St. Bartholomew's Hospital as the result of drawing a tooth. From these we might gather that the patient, a girl aged fourteen years, went to the hospital, had the tooth extracted, was detained, and died suddenly in hospital the next day from rapid inflammation of the brain which had escaped the diagnosis of the physicians under whose care she was. Inquiry shows that the case was indeed an obscure one and remained so. After the extraction of the tooth the girl went home, became ill two days later, and was admitted to the hospital on the third day in a nearly unconscious condition and with severe constitutional symptoms. She developed risus sardonicus and chronic convulsions, and later in the day tonic convulsions and opisthotonos, with intervals of complete relaxation. No definite diagnosis could be made, though tetanus and strychnia poisoning were duly weighed. She died suddenly during the night after admission, and the necropsy showed merely intense congestion of the brain, doubtful indications of meningitis, and some minute recent vegetations on the mitral valve. The coroner ordered no examination of the contents of the stomach, though these had been reserved. Cases such as this are by no means unknown and have baffled the diagnosis of many physicians, but no good end is served by dishing them up inaccurately for the lay press.

A JENNER RELIC.

THE immortal Jenner was a many-sided man, but outside the profession he is best known as "the man who invented vaccination." An interesting relic of this "person" of Jenner has been presented to the Royal College of Surgeons in the shape of Jenner's silver lancet-case and lancets. The donor is Mr. E. Wadams of Great Malvern, and the relic was presented to him by an old patient whose grandfather was Jenner's assistant. This case bears Jenner's initials and the lancets his name, and it can be seen in the Museum of the College along with the other Jenner relics.

COÖPERATIVE EDUCATIONAL TRAVEL.

THE following is a portion of the title page of a pamphlet sent to us by a correspondent: "Coöperative Educational Travel, by Henry S. Lunn, M.D., B.Ch., Fellow of the Medical Society of London; and J. T. Woolrych Perowne, M.A., late Classical Scholar, Corpus Christi College, Cambridge." Truly times have changed. In old days people never started on a journey with the idea of being educated. Of course, if they travelled in a proper manner they were educated, but the primary objects of travel were either to visit the Holy places, or amusement, or both. Of pilgrims in the first sense there are many examples. Early travellers for travel's sake are rare, but a notable instance of the combined pilgrim is the astounding liar who wrote the immortal travels of Mandeville—if, indeed, he ever travelled at all. Somehow the title "Educational Travel" takes away the romance of travel. It savours too much of those educational games which appear at intervals—and to judge by this prospectus, everything is made far too luxurious. Roughing it is half the pleasure of travelling. To show what an old time journey was like—a journey undertaken when a pilgrimage was a real act of a very lively faith—we recommend a perusal of a little-known work, an "Evagatorium" by Brother Felix Fabri, to the writers of the pamphlet. It is not written in good Latin, but is full of wisdom. He quotes a remark made by a "prudens Comes" to the effect that the journey to the Holy Land "nimis fore periculosam illis, qui levitate ducti, aut curiositate, aut seculi pompam, aut quandam vilem ac transitoriam vanitatem, finem ejus præstituerint." Now hear the pioneers of coöperative educational travel:—

"*The twenty-one guinea cruises.*—For the sake of clergymen who can only spare three Sundays from their parishes and professional men whose busy life will not allow a longer vacation we have planned two short cruises to Palestine and Egypt, calling at Sicily and Malta, which will afford the opportunity of a brief visit to the Holy City and the Pyramids to those to whom it would not otherwise be possible. The days of rest on the steamer will obviate any sense of hurry, and the time allowed for Jerusalem and Cairo is long enough to give opportunity for treasuring up never-to-be-forgotten memories of historic scenes."

The *Midnight Sun*, the chartered steamer, is indeed a floating palace. We quote from the prospectus:—

"The s.s. *Midnight Sun* is one of the finest pleasure yachts afloat and is a magnificent steamer of 3188 tons register and

Digitized by Google

3500 horse-power. Her passenger accommodation is exceptional. All cabins on the main deck are fitted up with large port-holes. The steamer is lighted throughout with electricity and fitted with electric bells. There are numerous hot and cold water baths for ladies and gentlemen, and all the cabins are supplied with hot and cold water. The majority of the cabins are arranged for two persons only and there are no upper sleeping berths, all berths being on the same level opposite each other. The dining saloon is eighty feet in length, and there is a smoking-room on the upper deck which will seat 100 people. There is also a drawing-room and music saloon, and a ladies' sitting-room on the upper deck. The steamer's launch is placed at the service of the passengers in the ports. The fare: ..... coffee and biscuits in the early morning, breakfast, lunch, afternoon tea, dinner, coffee after dinner, tea, at 8.30 P.M. All these meals are maintained while staying in port. A dark room is provided for the use of amateur photographers."

Brother Fabri, who had no ideas of coöperative education, went in a very different way. We cannot quote his account of the galley, but if the pamphleteers will read his chapter, "De inquieta dormitione peregrinorum in navi," they will see what a pilgrimage used to be like. "Multis noctibus fui, quod nunquam clausi oculum," says the unhappy Fabri.

PROSECUTIONS UNDER THE DENTISTS ACT.

THE *Western Mail* of May 23rd reports that two men have been fined at Newport (Mon.); the one, Walter Frederick Joll, for "unlawfully taking and using the name, title, addition, or description of dentist." One witness testified that the defendant at Messrs. Goodman's consulting-room said he was a dentist and drew a tooth for him (the witness). The offence was admitted and an undertaking given that it should not recur. A fine of 40*s.* and costs was imposed. The name of the other defendant was Moses Abel. He described himself to one of the witnesses who applied to have a tooth stopped as "a qualified dentist." The defendant's counsel, Mr. C. J. Jackson of Cardiff, tried to show that it had not been proved that his client used the title of dentist and that the witness called had been merely sent to entrap him. The evidence showed that the defendant had been fined on a previous occasion for practising as a dentist and advertising himself as such. The magistrates considered the case proved and inflicted a fine of £5, with the alternative of twenty-eight days' imprisonment. The magistrates declined to state a case.

THE BACTERIOLOGICAL DIAGNOSIS OF MALARIA.

IN the May number of *Archives de Médecine Navale et Coloniale* Dr. du Bois Saint-Sevrin has a short paper on the best way to identify the presence in human blood of the parasite which M. Laveran regards as the exciting cause of malarial fever. Dr. Saint-Sevrin, who is Professor of Bacteriology in the Naval School at Toulon, believes firmly in the specific character of the alleged hæmatozoa and, manifestly ignoring some recent developments, even goes so far as to assert that for some years the fact has not been seriously contested. He thinks that the reason why so many conscientious observers fail to find the parasite is because they follow defective methods of research, being misled by their habitual guides. The writers of treatises on microscopical procedure, while correct for the most part, nevertheless copy each other in perpetuating certain erroneous indications which tend to lead neophytes away from the proper path. For example, they all maintain that the patient whose blood is to be examined must not have taken any quinine for a considerable period, but in upwards of 100 cases all taking the alkaloid Dr. Saint-Sevrin never once failed in demonstrating the specific agent. It is essential, however, that the blood for examination should be drawn at the commencement of a malarial paroxysm. Another erroneous indication consists in recommending the employment of fresh blood without the use of staining re-agents. It is true that by this method alone can the flagellated bodies be demonstrated; but these, though academically interesting, are not essential from a diagnostic point of view. The small, recently developed bodies almost entirely free from pigmentation are what we have chiefly to depend upon for purposes of identification, and even with experienced observers there is often great difficulty in detecting them when staining material is not employed. During the period of apyrexia in a patient who is taking quinine regularly the hæmatozoa, as a rule, cannot be demonstrated in peripheral blood; they only make their appearance on the advent of a febrile paroxysm. The writer endeavours to account for this by the hypothesis that the parasites are momentarily lodged in the spleen, but the explanation is scarcely all-sufficing. Dr. Saint-Sevrin's paper, which is illustrated by an admirable coloured plate drawn by M. Boyer, terminates with the following conclusions:—1. Double staining with eosine and methylene blue constitutes the most favourable procedure for a rapid examination of paludal blood. 2. Canada balsam forms the best mounting for preserving the preparations. 3. Bacteriological examination should invariably be undertaken in all doubtful febrile cases. 4. In many cases prognosis and treatment cannot otherwise be established.

THE FUNERAL OF SIR J. RUSSELL REYNOLDS.

ON June 2nd the funeral of the late Sir John Russell Reynolds took place at Owlpen, Gloucestershire, the first part of the burial service being read at St. Peter's, Vere-street, by the Rev. Prebendary Harry Jones and Canon Page Roberts. Lady Russell Reynolds attended with the Rev. Dr. Henry Reynolds, elder brother of the deceased, as chief mourners. There were present, in addition to the late baronet's relations, General H. Lynedoch Gardiner, representing Her Majesty the Queen; Sir R. Quain, President of the General Medical Council, and Mr. Wheelhouse, representing the General Medical Council; Dr. Samuel Wilks, President of the Royal College of Physicians of London, and Mr. Christopher Heath, President of the Royal College of Surgeons of England, while these bodies were further represented by Sir Dyce Duckworth, the Treasurer, and Dr. Edward Liveing, the Registrar, of the Royal College of Physicians, and Mr. Reginald Harrison, Senior Vice-President of the Royal College of Surgeons; Mr. Ward Cousins, Sir William Priestley, M.P., Mr. H. T. Butlin, Dr. Holman, Mr. Macnamara, and Mr. F. Fowke, representing the British Medical Association; and Dr. Goodall, representing the Melbourne and Victoria Branch of the British Medical Association. Among others present were Sir William Broadbent, Dr. Barlow, Dr. Lauder Brunton, Dr. Buzzard, Dr. Cayley, Dr. Coupland, Professor Corfield, Sir J. Erichsen, Sir J. Fayrer, Sir W. Flower, Sir W. Foster, M.P., Sir A. E. Garrod, Dr. Garrod, Dr. Hare, Dr. S. Hutchins, Mr. Victor Horsley, Mr. Shirley Murphy, Dr. Stephen Mackenzie, Sir James Paget, Professor Burdon Sanderson, Mr. J. Tweedy, Dr. Whipham, Dr. Theodore Williams, Captain Arthur Reynolds, and Mr. G. W. E. Russell. Mrs. Best (sister of the deceased) and Mr. Best, Mrs. J. S. Vaizey (sister) and Mr. Vaizey, Rev. J. H. and Miss Best, Mr. K. G. R. Vaizey and Miss S. E. Vaizey, Mr. and Miss Sharp (nephews and nieces of the deceased), Canon Reynolds, Mr. Talbot Baines, and Mr. A. Baines, Mrs. Martin-Leake and Mrs. Trent-Stoughton (sisters of Lady Russell Reynolds), Messrs. Martin-Leake and the Misses Martin-Leake (nephews and nieces), were also present at St. Peter's, Vere-street. After the lesson the body was conveyed to Paddington and thence by train to Frocester, the station for Owlpen, for the

Digitized by Google

conclusion of the service. The Vicar of Owlpen met the procession and recited the commendatory portion of the service. Dr. Sedgwick and Mr. Fowke represented the British Medical Association at the grave.

HOMES FOR THE DYING.

ANYONE who has ever worked in a hospital must necessarily have been struck with the need that exists in London of a home for the dying. It is impossible, and indeed would be unfair, for an ordinary hospital to take in incurable cases; but, so far as we know, there are but three institutions in the whole of London open to this class of case. The oldest is the Hospital of St. John and St. Elizabeth in Great Ormond-street; then comes Freidenheim, near the Swiss Cottage; and, latest of all, the Hostel of God, 82, The Chase, Clapham. All these institutions do excellent work, but it is specially for the last that we now speak. In aid of its building fund a concert will take place on June 9th at Stafford House. Tickets £1 1*s.* each (two for £1 10*s.*) or 10*s.* 6*d.* each (three for £1 5*s.*) may be obtained from Miss Erskine, Speaker's-court, Palace of Westminster, or from the following: Messrs. Lacon and Ollier, 168a, New Bond-street; Messrs. Keith and Prowse, 48, Cheapside; and Messrs. Larner and Stokes, 42a, Chester-square; or subscriptions may be sent to Mr. W. Portlock-Dadson, 281, Strand, W.C.; Mr. W. Hoare, The Brewery, Lower East Smithfield, E.; or to the account of the "Home for the Dying," Messrs. Hoare, 37, Fleet-street, E.C.; to Colonel Hardy, 35, Wellington-street, Strand, on account of the "Home for Dying"; or to the Sister Superior, the Hostel of God, 82, The Chase, Clapham, S.W. In our columns of May 27th, 1893, will be found an earnest appeal from Mr. T. Bryant, and no more words of ours are necessary to impress upon the charitable the excellent work which such institutions carry on.

"A RIVER VOYAGE THROUGH NORTHERN SWEDEN."

WE have received from the Swedish Touring Club a pamphlet in English bearing the above title. It is freely illustrated and describes the scenery of some of the large rivers which flow into the Gulf of Bothnia from Sweden, and it gives detailed instructions as to the routes, the objects of interest, and the average expenses of the journeys which it sketches out. For some years the Swedish Touring Club has been doing excellent work in opening up to travellers the less frequented districts of Sweden, and the northern or forest regions of that country are among the most beautiful spots in Europe. It is strange that while Norway has for years been overrun with tourists from this country Sweden should remain so long unknown, for unknown it is to the vast majority of English people. Those who have penetrated into the country invariably return full of enthusiasm as to its charms, but when they urge their friends to go there likewise for a holiday their praises too often fall upon deaf ears. It is not at present the fashion to go to Sweden, that is all. The trip from Stockholm up the Baltic coast by steamer to Sundsvall occupies seventeen hours, for the first five of which the vessel is steaming smoothly among the countless islands which form an archipelago round the entrance to Stockholm. This journey among the islands is full of beauty, the steamboats are models of comfort and cleanliness, and the food is uniformly excellent. The traveller is always safe to trust to the catering on board these coasting steamers, because the Swedes are a restaurant-loving people, and insist upon having good food and refreshments wherever they go, so that all anxiety as to commissariat may be dismissed when on board of, or even within reach of, a Swedish passenger boat. On reaching Sundsvall the steamer may be taken up the Indals River, returning later by the Angerman River, and so back to Stockholm, or the traveller can prolong his visit inland. The inland districts are characterised by mountains, pine trees, lakes, and rivers, but among the wilds there exist excellent hotels and health resorts. The fresh and stimulating air, the bright daylight, and the intensely vivid green of the grass and the foliage all tend to make these upland summer resorts excellent. In Sweden the English are always welcome; scrupulous cleanliness prevails, living is cheap and good, meals are served for the most part in the open air, and there is good music to be heard almost everywhere. We strongly recommend our readers who are in search of a new holiday resort to try Sweden, for they will be surprised and charmed with it and invigorated as well.

OVERWORK AND EMPLOYERS' LIABILITY.

IT is not only in connexion with the management, or rather the mismanagement, of railway service or of retail business that we are brought in contact with the mischievous effects of overwork. A variety of other callings are liable to be disorganised by the same form of excess. Seldom indeed, however, do we find that either the long-continued strain of labour or its disastrous consequences are so palpably evident as in a case recently investigated at the London Hospital. A carman had fallen, while asleep, from his driving seat, and had sustained a fatal fracture of the skull. On examination it transpired that the man had been at work for thirty-six hours consecutively, either cutting or carting garden produce for his employer, and that it was intended that he should work for twelve more hours before taking rest. It is not surprising that the verdict of accidental death passed in this case was accompanied by important modifications. The hazard imposed upon men employed in responsible and heavy duties with such unscrupulous disregard for the absolute needs of existence is not greater than the danger which is, by the same action, thrust upon the general public. Lessons like that conveyed by this so-called accident, moreover, are hard of acceptance unless it be understood that they shall effectively teach the practice of prevention. We need hardly remind our readers that in order to secure this end more is required than the mere censure of a jury. Accidents in which one party is to be blamed for the injury of another may well constitute a ground for liberal compensation. In such a case as that before us this form of expiation is the least that should be regarded as consistent with the legal duty of a culpable employer.

THE MANUFACTURE OF EXPLOSIVES.

THE twentieth annual report of Her Majesty's inspectors of explosives just published is on the whole a satisfactory one, especially when regard is had to the great number of new explosives invented during the last few years. The number of deaths from accidents by fire or explosion in manufacture was ten only, which, although above the average for the past ten years marks an extraordinary and most satisfactory contrast with the figures which obtained before the Act came into operation (1876). These satisfactory results, it is stated, have been accomplished without any undue or even inconvenient interference with the trade. Makers at home have complained from time to time that the severity of the Act has given a better chance to makers abroad. Of recent years, however, complaints on this head have been less frequent, owing chiefly to the fact that during the years which have elapsed since the English Act was passed other countries have introduced laws and applied regulations affecting explosives based on our own, but as a general rule they have been of greatly increased

Digitized by Google

stringency. In their remarks upon the slight explosion which occured in the manufacture of cordite at Waltham Abbey on April 22nd., the inspectors were not able to trace the cause of the ignition with certainty. It is remarkable, however, as they point out, that the bulk of the paste fell out of the broken cylinder intact and that the cordite present in the building was not ignited. Only one ounce of the paste in the cylinder exploded, although the charging press from which the cylinder was filled contained about thirty pounds of cordite paste. Bearing in mind the large increase in the number of factories, the increased output, the number of hands employed, the greater resulting chances of accident, and the increase in the enormous number of nitro-compounds made and imported, the Act, as shown by the present report, is evidently doing good work.

LUNATICS IN WORKHOUSES.

THE Local Government Board have just issued a circular to boards of guardians with special reference to the medical examination of lunatics received into, or removed from, workhouses. The circular appears at an opportune moments when much is being written and said concerning the care of paupers. Instances of failure to make the requisite examination and to record results where examination has been made have come under the Board's notice, and these probably account for the issue of the present document. Careful examination by the workhouse medical officer is enjoined immediately on the admission of a lunatic and immediately prior to removal or discharge; any examination in the latter case made even on the day previous to discharge is to be repeated on the actual date when the patient leaves the institution, special regard being given to any bruises or other injuries on the person. The physical condition of the patient to be removed is also to be a point of consideration by the medical officer. Such examination is in nowise to replace that called for by the Lunacy Act of 1890, where a private medical practitioner is in question. Another point refers to attendance on lunatics detained in workhouses. The Board consider that all lunatic, should be both by day and by night under the immediate charge of paid officers, and that pauper assistance, when it is impracticable to altogether dispense with it, should be under the closest supervision of paid officers. We look upon this as a very important part of the letter, and trust that as time goes on the Board will insist more and more on the replacement of pauper attendance by that of properly appointed and remunerated officials.

MEDICAL HISTORY OF PEKING DURING THE WAR.

THE thirty-fourth annual report of the Peking Hospital[1] in connexion with the London Missionary Society for the year 1895, by Dr. Eliot Curwen, is interesting. He speaks highly of the activity and efficiency of two native students—Mr. Li Hsiao-ch'uan and Mr. Liu Paoching—between the departure of Dr. E. T. Pritchard and his own arrival. The popularity of the hospital and dispensary seems to increase, the visits paid being 4000 in excess of those of any previous year; thus 33,253 visits were paid by 14,604 patients in 1895. To patients at their own homes 278 visits were paid and 162 were treated in the wards. Unfortunately, we presume for want of funds, only two out of three wards for males were in use. There was a memorable outbreak of cholera in Peking in 1895. Dr. Curwen speaks of it as the most fatal epidemic of the century. It is estimated to have attacked half the houses and to have killed 75,000 of the inhabitants. Few cases were brought to the hospital. If not quickly fatal they were mostly treated by native medical men with acupuncture of the larger joints or of the tongue. As a consequence of this treatment many afterwards became patients at the hospital suffering from acute suppurative inflammation of the larger joints. The prevalence and mortality of cholera need occasion little surprise when we learn that the roads were watered with the contents of open sewers to save the trouble of drawing water from the wells. The Chinese recognise that unboiled water and green fruit generally are ready carriers of the disease. Dr. Curwen acknowledges the willing help in many ways of Dr. S. W. Bushell of the British Legation. One of the most blessed influences in such countries must surely be that of the members of our own profession, whether official missionaries or not.

THE BIRMINGHAM HOSPITAL SATURDAY FUND.

THE Executive Committee of the Birmingham Hospital Saturday Collection has received a valuable gift in the shape of a seaside home for children. The generous donor, who does not wish his name to be disclosed, has handed over a mansion called Bryn Marle, between the two convalescent homes for men and for women already in use. He is prepared to furnish and maintain it free of cost for the first twelve months.

THE HEATH SCHOLARSHIP

THE Heath Scholarship has been awarded to Mr. G. P. Newbolt, M.B. Dunelm., F.R.C.S. Eng., for his essay on the Surgical Diseases of the Jaws. The prize is £200. It is awarded every second year to the writer of the best essay upon some surgical subject selected by the trustees of the Heath Scholarship Fund, and only graduates in medicine or surgery of the University of Durham can compete for it. The subject for the next competition is Congenital Deformities, their Pathology and Treatment. The essays must be sent in on or before the last day of March, 1898. Mr. Newbolt is the first winner of this valuable scholarship.

STATISTICS ON WEIGHT OF INFANTS, SEX AND FŒTAL HEART-RATE.

STATISTICS of large numbers of cases are often useful to correct erroneous impressions on statistics from small numbers. A paper read before the Obstetrical Society of Boston on Feb. 18th of this year is interesting and valuable from this point of view as showing the results obtained from observations in a large number of infants as regards weight, sex and fœtal heart-rate.[1] Thus the assertion is often found in text-books that the fœtal heart-rate of girls is more rapid than that of boys. It appears to depend on the statement made in 1859 by Frankenhauser that the average fœtal rate in boys was 124, in girls 144, and this he obtained as a result of fifty observations. It is no wonder that predictions of sex based on such a small foundation should be disappointing. Taking a thousand cases at full term at the Boston Lying-in Hospital, the average rate of the fœtal heart was as follows: 500 males, 140·26 per minute; 500 females, 141·83. This difference of one and a half beats is, of course, valueless for prophetic purposes. Let us hope that Frankenhauser's statement will no longer be copied into the text-books. The average weight of these 1000 full-term infants was as follows: 500 male infants, 7 lb. 8·9 oz.; 500 female infants, 7 lb. 5·1 oz. It might be said that the slightly slower heart-rate in the boys depended on the slightly heavier weight of the male sex. It is interesting to note, however, that some of the very heavy babies had rapid hearts, and *vice versâ*; so that no individual prediction of the weight of the child could be made by the heart-beat. The variation in the rate of the heart-beat at different periods in the labour is also

[1] Boston Medical and Surgical Journal, May 14th, 1896.

Digitized by Google

a commonly observed fact. Of 7515 deliveries at the Boston Lying-in Hospital, the heaviest child was a female weighing 12 lb. The infants were all carefully weighed, and the actual weight without clothing was obtained. The following table shows the number of heavy children over 10 lb. in weight born at the hospital:—

	Male.	Female.
10 to 11 lb.	46	25
11 to 12 lb.	10	5
12 lb.	—	1
	56	31
Total	87	

The records of the out-patient department were not considered sufficiently reliable to examine for this purpose. The largest infant, however, in which the record could be trusted weighed nearly 13 lb. This child was carefully weighed in scales that had been tested.

FOR THE FADDIST.

THE medical officer of health for the St. Olave District has issued a report to the Board of Works for that district on the increasing neglect of vaccination in the union. In 1881 the proportion of children, says Dr. Bond, unaccounted for in regard to vaccination (including cases postponed) in the Metropolitan unions was only 5·7 per cent. of the total births. In 1891 this proportion had risen to 16·4 per cent. In the St. Olave Union the corresponding rates were 4 1 and 15·3 per cent. Of the 676 cases of small-pox that were removed to the hospital ships of the Metropolitan Asylums Board during the six months ending Dec. 29th, 1895, there were 113 under ten years of age, and 68 over ten years and under fifteen years. Of the 113 under ten years of age 104 were not vaccinated, 7 were vaccinated, and in 2 cases there was no history in regard to vaccination. Of the 68 between the ages of ten and fifteen 36 were not vaccinated, 31 were vaccinated, and in one case there was no history in regard to vaccination. Not one of the 68 patients over ten and under fifteen years of age was stated to have been re-vaccinated. The strongest practical evidence that small-pox can be stamped out by vaccination and re-vaccination is supplied by Germany, for since the year 1874 re-vaccination before leaving school has been compulsory, and during the last ten years small-pox has been almost extinct, being at the rate of only one case per million inhabitants; and these few cases are those of foreigners or natives who have not been re-vaccinated. Comment on these figures is needless, and we can only hope that when the report of the Royal Commission on Vaccination does see the light it will insist not only on vaccination but on re-vaccination.

THE secretary of the Royal College of Surgeons of England has issued notices for a meeting of the Fellows of the College, to be held at the College in Lincoln's-inn-fields on Thursday, July 2nd next, at five o'clock. The last day for the reception of notices of motion by the secretary is Thursday, June 11th next, and motions must be signed by the mover or by the mover and other Fellows.

WE are informed by the Colonial Office that a telegram has been received from the Governor of Hong-Kong stating that eighty-one fresh cases of bubonic plague occurred in the colony in the week ending June 1st and that the number of deaths from the plague during that period was seventy-three.

A COMPETITIVE examination for twenty-five commissions in the Army Medical Staff will be held on Aug. 7th next and following days. Particulars thereof will be found in our advertisement columns.

THOMAS WAKLEY,

THE FOUNDER OF "THE LANCET."

A BIOGRAPHY.[1]

CHAPTER XXII.

The Revolt of the Members of the Royal College of Surgeons of England.—Wakley's Consistent Attitude.—The Navy and the College.—The Members' Petition in the House of Commons.—Sir Robert Peel for the Defence.—The Decision of the House.

IT would serve no purpose to trace all the steps of the duel that now took place between the reformers and the College authorities. The part that was played in it by Wakley was throughout consistent and vigorous. The official refutation was treated by him with complete ridicule, inasmuch as it refuted nothing, but only added fresh insults to those which had already been accepted by the Members for years and were now for the first time being resented. In particular, the last paragraph but one of the unfortunate document came in for scorn. The statements that the subversion of the Charter would lead to the election to offices of control and responsibility of persons "who for the most part exercised the professions of apothecaries and accoucheurs," in which case the institution would soon cease to be a College of Surgeons or Surgery, while "a system of continual intrigue and cabal amongst the profession in general would be introduced," furnished Wakley with an admirable text upon which to address the profession at large, and one of which he was not slow to avail himself. Such words he held to constitute a direct insult to the general practitioners of England as well as a distinct attempt to exercise an illegal power. While declaring in uncompromising terms that the general practitioners were much more capable of conducting the affairs of their corporation than were many of the twenty-one councillors elected for life, and frequently displaying evidences of senility while occupying their offices, he pointed out that the Charter—the infamous Charter under which this oligarchical and irresponsible little body claimed the right to control the affairs of the Members—contained no provision for the limitations which the refutation of the College attempted to lay down. There was not a word in the Charter implying any disability on the part of an apothecary or an accoucheur to occupy a seat either on the Council, the Court of Examiners, or even the Presidential bench, and he accused the existent Council of attempting to read into the Charter already upholding no interests but their own unwritten clauses still further securing to themselves all the benefits, honorary or pecuniary, in the power of the College to bestow. This formed an admirable rallying cry for the Members and it was recognised by them as such, THE LANCET receiving at the time an enormous access of regular readers and subscribers among the general practitioners of England, who recognised in Wakley the guardian of their interests, the man who was not only prepared to see that they received some substantial return for their fees, but also that they were treated with the respect due to them as the persons who paid.

It was not until the last day of 1826 that the petition to the House of Commons for the abrogation of the Charter reached its final stage, so that signatures could be invited for it. Spontaneous as had been the revolt of the Members against their rulers, and unanimous as had been their

[1] Chapters I., II., III., IV., V., VI., VII., VIII., IX., X., XI., XII., XIII., XIV., XV., XVI., XVII., XVIII., XIX., XX., and XXI. were published in THE LANCET, Jan. 4th, 11th, 18th, and 25th, Feb. 1st, 8th, 15th, 22nd, and 29th, March 7th, 14th, 21st, and 28th, April 4th, 11th, 18th, and 25th, May 2nd, 16th, 23rd, and 30th respectively.

Digitized by Google

strongly-worded resolutions of remonstrance at the general meetings, the movement would have ceased at the mere passing of these resolutions had it not been for Wakley's energy, desire for justice, and, it must be admitted, personal implacability. Mr. Lawrence was satisfied with the commotion that had been caused in the comfortable breasts of the Council and from personal reasons was desirous of peace. Many of the leaders in the agitation were also ready to lay down their arms on the promise of some slight concession. But not so Wakley. He held the meeting to their pledged course, declaimed against the perpetual delay in the preparation of the petition, and was finally able to announce that the means of redress had at last been brought within reach of the Members, for the document was lying ready for signature at Freemasons' Tavern. During the eleven months that elapsed between the general meetings and the completion of the petition for signature the columns of THE LANCET had regularly contained leading articles or correspondence bearing upon the strained relations between the Members and the Council. Generally the intent of these articles and communications was very clear; indeed, where Wakley's, Wardrop's, or Lawrence's pen was speaking the terms used were uncompromising to a degree, yet occasionally the connexion between the information given to the public and the actual terms of the internecine quarrel in the profession was not so distinct. But Wakley was not a careless editor nor a promiscuous vilifier of his opponents, and all the notice taken by THE LANCET of the attitude of the Council had a definite reason. When the petition at last made its appearance the prominence given to certain matters not obviously germane to the subject at issue became manifest. Wakley, for instance, had dwelt at length on the fact that the Navy had refused to accept the diploma of the College as sufficient to warrant the advance of the medical men holding it from assistant surgeon to full surgeon. He also inserted from time to time little exposures of quacks and advertising charlatans who claimed to be, and occasionally were, on the official list of Members of the College. Both these points were brought to the notice of his readers with definite intent, as will be seen from the opening words of the petition. Wakley also stirred up the provincial surgeons to present separate petitions of their own in protest against the wrong done them and their hospitals by the recent by-laws of the College, and in two places at least his words bore fruit. For the medical men of the neighbourhoods of Bristol and Winchester instructed their knights of the shire to speak in Parliament in support of the Members' petition.

The petition was an able document, bearing, however, no trace of labour or research, so that it is difficult to understand why it should not have been ready for signature until the end of the year. The resolutions of remonstrance adopted at the general meetings at the Freemasons' Tavern in the spring[2] will sufficiently indicate the lines upon which it was drawn, as it was designed to meet those specific grievances. The declared object for which the Charter of 1800 was granted was "the due promotion and encouragement of the study and practice of the art and science of surgery," the principal means by which these objects were to be brought about being by the conduct of examination into the qualifications and education of candidates for admission into the College or into the medical department of the Navy and Army, the obvious supposition being that the certificates of the College would enable the public to distinguish between the expert and the pretender. The petition then pointed out that the charter had consigned the whole management of the College to twenty-one persons, who, being elected for life themselves, had the privilege of electing whomsoever they liked, also for life, to fill any death vacancies; that these twenty-one persons appointed ten of their own body to form a Court of Examiners and were not accountable to the Members for the appropriation of the funds, nor for any other of their proceedings which were conducted in private. The petition next showed that the twenty-one governors of the College had a direct interest in keeping all the emoluments to themselves and that they did so by preventing other persons than the Court of Examiners and personal friends of that Court from delivering official lectures to the students, upon which followed naturally a representation of the grievances concerning the new by-laws as to the sources of official certificates of attendance at lectures. We now see Wakley's object in inserting matter that must have seemed at the time that it was printed mere irrelevant abuse. *He knew what the petition was going to be.* His object in alluding to the action of the Navy when that department refused to accept under certain circumstances the diplomas of the College as proofs of scientific efficiency is now transparent. One of the main reasons for the existence of the College, one of the specified objects that George III. had before him in granting to the discredited corporation a Royal Charter whereon to begin a new life, was that the College should accept the responsibility of supplying the military and naval services with efficient surgeons. In this the College must be held to have failed. A second main reason for the grant of the royal charter had been to safeguard the public against quacks, the duty devolving on the College to discriminate between the charlatan and the true man of learning. The object of giving prominence to the fact that there were notorious quacks, persons dealing in secret and disgraceful remedies, and whose names were on the official list of the College, now leaps to our eyes. It was to show that in another direction the College had been found wanting to the implied contract between its original governors and the King.

On June 20th, 1827, Mr. Warburton, whose name is more closely associated with the Anatomy Bill of a little later period, presented the petition of the Members to the House. In his speech in its support Mr. Warburton pointed out that in 1797, when the former Corporation of Surgeons were attempting to obtain from Parliament a re-establishment — the parent corporation having ceased to exist in consequence of some irregularities in its procedure — Lord Thurlow persuaded the Lords to scout the Bill because it contained certain clauses inimical to the interests of the Members. These same clauses were now, he said, in active operation under a Royal Charter against the Members, who therefore prayed for relief in the full trust of obtaining it. Mr. Warburton then recapitulated almost in the words of the petition the various tribulations of the Members as exemplified by the six strong resolutions of remonstrance passed at the general meeting,[3] and concluded by moving for a return from the Royal College of Surgeons of England of all public money lent or granted to the College from 1799 to the present time. He specified the grants he required to have information upon as being those made for the purchase, building, and repairing of the College, and for the purchase of the Hunterian Museum. He also desired that the regulations under which the Members of the College and the medical students were admitted to the Hunterian Museum and to the library of the College should be laid on the table, as well as the numbers of persons who had been examined by the College since 1800. He required also an account of all moneys received by the College from its Members and a detailed statement of the appropriation and

[2] See Chapter XX. of this biography.

[3] Loc. cit.

Digitized by Google

expenditure of these sums and of the sums granted by the State. After a few words from a Mr. Smyth, who said that the petition was the work of interested persons and was based upon no better foundation than feelings of personal pique, Mr. Peel, the Home Secretary (afterwards Sir Robert Peel, the great statesman), rose to speak in behalf of the College. The line of defence adopted was practically a confession of guilt. Mr. Peel, who was a trustee of the Hunterian Museum, said that he had discussed with the Council of the College every subject of complaint preferred in the petition, and that many of the causes no longer existed, and that every one of them that appeared reasonable would be in time removed. The back-door entrance was done away with, the catalogue of the museum was being prepared, and a quarterly statement of the financial affairs of the College would for the future be made public. Mr. Peel did not consider "that there was the slightest ground of accusation against the College," but he was willing to support Mr. Warburton's motion, after the explanation the House had heard of his vote, because he considered Parliament had a right to be informed of the proceedings of an institution which had received large grants of public money.

As Wakley pointed out the following day, Mr. Peel's speech was a very illogical performance. Certain complaints were made concerning the action of the Council; therefore a petition was presented to Parliament begging for an alteration in the Charter which sanctioned the abuses. Mr. Peel rose and admitted that the complaints were being attended to and would receive further attention, and yet said that the petition was presented on no proper grounds of accusation!

The House acceded to Mr. Warburton's motion and the College was called upon to render an account of its stewardship. A temporary victory was thus gained by the Members.

(To be continued.)

THE FIRST QUINQUENNIAL CENSUS IN LONDON.

THE Registrar-General, in his return for the week ending Saturday, May 23rd, briefly notes the results of the recent London census, taken at the end of March last under the provisions of the London (Equalisation of Rates) Act, 1894. Especial interest attaches to the results just published from the fact that the recent census is the first quinquennial census that has been taken in this country. Based on the assumption that the rate of increase of population that prevailed in London during the ten years 1881–91 had since been maintained, the Registrar-General had estimated the population of the metropolitan area known as Registration London in the middle of this year at 4,435,955, whereas the revised estimate for the same date, based upon the numbers enumerated on March 29th last, now adopted by the Registrar-General, is 4,421,492, and 14,463 below the previous estimate. In other words, the recent census shows that the rate of increase of population within Registration or Inner London since 1891 has been smaller than the rate that prevailed during the ten years 1881–91. This recent decline in the rate of increase in Inner London need cause no surprise, since it was pointed out in the last census report that the increase per cent. of population within this area, which had been 16·0 and 17·3 in 1861–71 and 1871–81, fell to 10·4 in 1881–91. Indeed, the actual decline of population in Central London, owing to the substitution of business premises for dwelling-houses, and the migration of the residents to suburban neighbourhoods, a large proportion of which lie outside the arbitrary boundary of Inner or Registration London, has long been in progress at an increasing rate. The population enumerated in March last in Inner London showed an actual increase of 199,528 upon the number enumerated at the previous census in 1891; the increase per cent. in the five years being 4·7, against 10·4 in the ten years 1881–91. The decline, therefore, in the rate of increase was not so great as it had been between 1871–81 and 1881–91. As regards the whole of London the error in the estimate of population, which this quinquennial census has enabled the Registrar-General to correct, was in reality very slight, and for general statistical purposes might be disregarded. When we come to consider the more distinctly local results of the census the value of the quinquennial figures, meagre as unfortunately are the details available, becomes patent. It is distinctly evident that in many sub-divisions of the metropolitan area the rate of increase between 1881 and 1891 afforded no trustworthy indication of the increase since 1891.

One of the most strongly marked features of the new figures is the evidence of the arrest of the rapid decline of population in the central districts. It was pointed out in the last census report that in eleven of the central registration districts the enumerated population showed an actual decline during the ten years 1881–91 equal to 7·2 per cent. in the aggregate and ranging from 25·5 per cent. in London City, 18·8 in Westminster, and 18·1 in the Strand, to 2·0 in Shoreditch and in Stepney and 0·8 in St. Pancras. In the five years 1891–96 the decline was changed to increase in three of these eleven districts—namely, in St. Pancras, Stepney, and St. George-in-the-East; while in each of the other eight districts the percentage of decrease showed a marked decline except in London City, where the decrease in the five years was 17·2 per cent., against 25·5 in the preceding ten years. In the aggregate of the eleven districts the percentage of decrease in the five years was only 1·0 per cent., whereas in the previous ten years it had been 7·2 per cent. The nineteen other registration districts which showed an increase in the ten years 1881–91 continued to show an increase during the five years 1891–96, but the percentage of increase, which had been 29·3 and 17·5 in the census periods 1871–81 and 1881–91, further declined to 6·6 per cent. in the five years ending with March last. The increase, with very few exceptions, showed a decline in each of these nineteen districts; the most noticeable exceptions were Whitechapel and Lambeth, in each of which districts the increase was proportionally far greater than it had been in the preceding inter-censal period. The most marked decline in the rate of increase naturally occurred in Fulham, Hammersmith, Hampstead, Wandsworth, Lewisham, and Woolwich, in which the percentages of increase had been exceptionally large in 1881–91. In Fulham and Hammersmith, for example, the increase in the five years 1891–96 did not exceed 15·4 per cent., against 74·0 and 64·5 in the two ten-year periods 1871–81 and 1881–91. It is much to be regretted, from a statistical point of view, that the scope of the recent census did not include Greater London, as, having regard to the continued decline in the rate of increase in Inner London, it would be full of interest to know whether the percentage of increase of population in Greater London, which declined from 22·7 in 1871–81 to 18·2 in 1881–91, is continuing to decline. For information on this point, however, it seems necessary to await the next national census in 1901. As a matter of fact, the recent census embraced the area of the Administrative County of London, which includes the hamlet of Penge (with a population in 1891 of 20,375), in addition to Inner or Registration London. It has long been a matter for serious regret that no measures have been taken to include Penge within Inner or Registration London, which would thus be made co-extensive with the Administrative County of London, the main obstacle to which appears to be that Penge forms part of Croydon Registration District and Poor-law Union.

THE annual meeting of the Incorporated Medical Practitioners' Association was held on May 14th at the Holborn Restaurant. The annual report showed a rapidly increasing membership and the formation of important branches in Devon and Cornwall and in Lancashire and Cheshire during the past year. A number of new by-laws providing for an extended organisation of the Association were passed, Dr. Bedford Fenwick was elected president, and the council and other officers were appointed for 1896–97. A considerable number of members and their friends dined together in the evening under the chairmanship of the late President, Mr. George Jackson, F.R.C.S., of Plymouth.

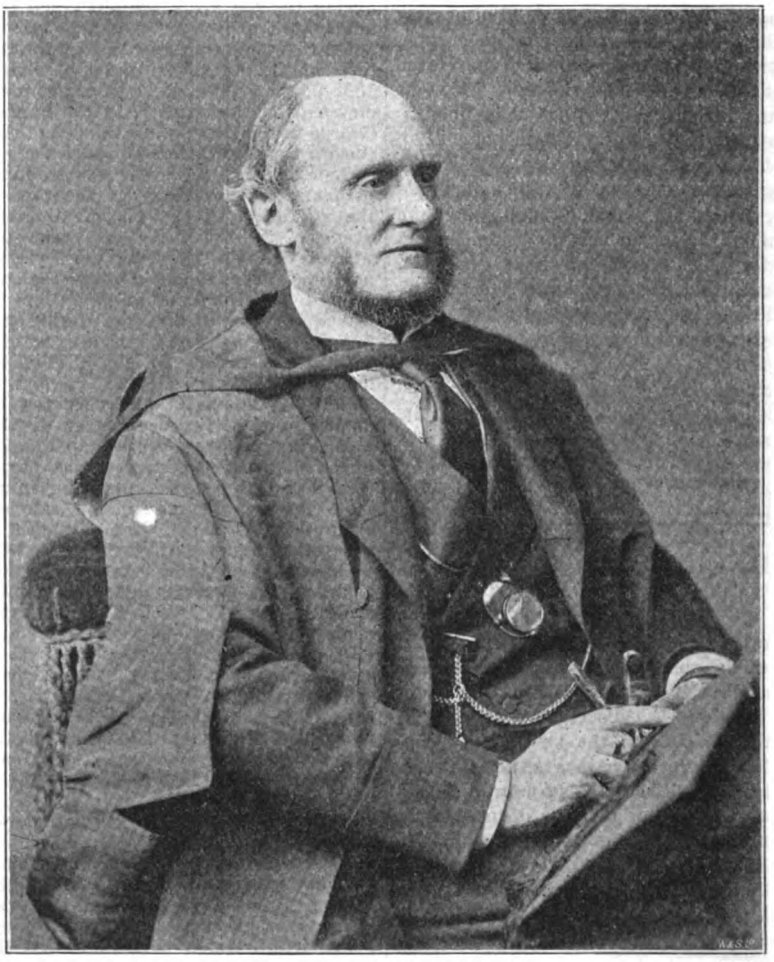
Obituary.

SIR JOHN RUSSELL REYNOLDS, BART., M.D., F.R.C.P. LOND., F.R S. LL.D. ABERD., LL.D. EDIN.,

PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION, PHYSICIAN TO HER MAJESTY'S HOUSEHOLD, CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, AND LATE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

WE deeply regret to announce the death of Sir John Russell Reynolds, which took place at his residence in Grosvenor-street on Friday afternoon last (May 29th). He had been failing in health during the whole of the present year, but no organic mischief having manifested itself it was hoped by his friends and medical advisers until the end that the great debility, which was the chief and for some time the only obvious sign of illness about him, would give way to rest, treatment, and change of air, and that a return to health would be established. These hopes have been disappointed, for in spite of the most watchful medical care and assiduous nursing the weakness steadily increased until, at the beginning of last week, a condition of extreme prostration was reached, from which he never rallied, but gently passed away in a condition of painless unconsciousness.



SIR JOHN RUSSELL REYNOLDS, BART., M.D., F.R.S.,
LATE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

John Russell Reynolds was the second son of the Rev. John Reynolds, a distinguished figure in the Nonconformist world, and the grandson of Dr. Henry Revell Reynolds, F.R.S., who was physician to Middlesex Hospital at the beginning of the century, Goulstonian Lecturer, Censor, Harveian Orator, and Elect of the Royal College of Physicians, and Physician in Ordinary to King George III. John Russell Reynolds was born at Romsey in Hampshire in 1828 and his early education was received at the hands of his father who had been captain of Westminster School and classical scholar of Oriel College, Oxford. Having decided to follow in the steps of his grandfather he proceeded in 1846 to University College, London, where his elder brother Henry (the Rev. Dr. Henry Reynolds, late principal of Cheshunt College) was already a distinguished student. His medical career was exceedingly brilliant. He obtained gold medals at University College in medicine, clinical medicine, and obstetric medicine and graduated in the University of London as University Medical Scholar and Gold Medallist in physiology, comparative anatomy, and medicine. With this record of successful performances and a high character for industry, conscientious work, and zeal, the young physician was marked out by his colleagues and tutors as a coming man, so that it was felt by all when he decided to leave London to practise in the country that he was renouncing a future of assured brilliancy. Dr. Russell Reynolds was not, however, a man of large private means, nor was his father able to afford him much pecuniary assistance, and the opening at Leeds of which he decided to avail himself on becoming qualified was attended with peculiar advantages for him, inasmuch as he had influential friends and relations in the town to whom the details of his promising career were well known. But, hardly had he settled down in Leeds when an unexceptionable opportunity for London practice presented itself to him. His great friend and brilliant teacher, Dr. Marshall Hall, F.R.S., the discoverer of the reflex functions of the spinal cord, decided to leave London and give up professional work, and his house in Grosvenor-street was offered to Dr. Russell Reynolds upon favourable terms. The house was familiar to him, for in his late student days he had been one of the half-dozen men who met weekly there to be less, perhaps, instructed than inspired by the prolific imagination of the greatest neurologist of the mid-century. He was at first anxious to avoid the responsibility of starting in practice in so conspicuous a manner and in so expensive a locality. He was satisfied with his chances at Leeds though the new prospect tempted him much. But his friends and his teachers were so urgent that he should lay aside modesty and come to London to command the success that lay ready to his beck that he accepted the surrender of Dr. Marshall Hall's lease of 38, Grosvenor-street and established himself there in 1852, in the house where he died forty-four years later.

Dr. Russell Reynolds was fortunate. He had not long to wait for recognition. In 1855 he was appointed assistant physician to the Hospital for Sick Children, Great Ormond-street, in 1857 assistant physician to the Westminster Hospital and Lecturer on Forensic Medicine in the school, and in 1859 assistant physician to University College Hospital. This appointment brought him back again (to his and their extreme pleasure) among his old teachers and friends, Sharpey, Walshe, Thompson, Jenner, Wilson Fox, Henry Thompson, and Erichsen, to mention a few whose names immediately recur to memory, and in this brilliant circle he was made entirely welcome, being

Digitized by Google

recognised, not only as a colleague most grateful to their sentiments, but as a powerful adjuvant to the teaching resources of the institution. In 1862 he became full physician to the hospital and Holme Professor of Clinical Medicine, and three years later he succeeded Sir William Jenner as Professor of the Principles and Practice of Medicine in the College.

He immediately made his mark as a lecturer. He was lucid, learned, informatory, and, above all things, original. Deeply read as well as practically expert, he knew the difficulties which lay before his hearers, and he took his own way to clear them up. With a command of French and German as well as of his own language, it was no trouble to him to find a new manner of saying old things or new examples elucidatory of old knowledge; consequently he was able to clothe the truisms with which all scientific lectures must abound, and the repetitions, without which they would be incomprehensible, in a perpetually novel and striking attire of ideas and words. And stress must be laid upon the fact that this display of subtle intelligence and verbal felicity was, as has been said, no trouble to him. Never was a lecturer less affected. Never did a public speaker hunt less or grope less for the allusion that should seem extraordinary or the quotation that should seem apt. There was with Dr. Russell Reynolds no necessity for effort and no concealed struggle—facts which accounted for the pleasure with which he was always heard by his audience. Fluently, accurately, and with absolute precision he taught his science, while, having his learning at his finger tips, his poetic similes and quaint, humorous illustrations made their natural appearance in his discourse and riveted in the memory of his hearers many a simple fact, as well as many an elaborate argument, that in the unilluminated page of the text-book had seemed without importance or, perchance, without meaning. His old pupils to this day speak of their attendance at Reynolds's morning lectures in medicine not merely as a part of their routine medical education to which they were forced to submit, but rather as an interlude in that education from which they reaped not only substantial assistance in their comprehension of medicine, but absolute intellectual pleasure and wider views of life.

Dr. Russell Reynolds's skill and eloquence were the outcome of his intimate knowledge of his subject and the wide range of his general culture, but that does not account for all his success in lecturing. These things would have given him the material, but his literary skill gave him the power of performance. For although, compared with many men of less eminence in the profession, he was not a voluminous writer, it was as an author that he won his spurs, and as an author that he justified in the eyes of the profession his early success as a consulting physician and his prompt election while still quite young to so many important medical posts. His first medical work was an essay upon Vertigo. This was an expansion of a short paper read before the North-west London Medical Society in 1854 and reprinted at the request of some of those present who recognised in it a genuine contribution to medical literature. The essay marked its author out at once as an observant clinician and a well-read neurologist. It was a sketch of the development of medical knowledge concerning the causes of rotatory movement, the phenomena being for purposes of clearness distributed into "vertiginous movements" and "vertiginous sensations." Although largely a historical *résumé* the author's reflections had the stamp of an original mind, while the clearness and grace of his style contributed to the value of his monograph. This essay was followed in the course of a few months by two larger works having the titles, "The Diagnosis of Diseases of the Brain, Spinal Cord, and Nerves," and "Tables for Diagnosis of Diseases of the Brain." These constituted at the time the most clear and explicit account of the diseases of the nervous system that had appeared. It was characteristic of the author's precision and modesty that, having defined the scope of the work as a collection of what was known, he made no attempt to increase the stock of individual pathological observations. He dealt with the things that were before the profession and reduced to their proper value such semeiological phenomena as had already been recorded in connexion with disturbances of the functions of the brain and spinal cord. These contributions to the literature of neurology were followed in 1861 by his book on Epilepsy. This was a brilliantly written application to medicine of the statistical method now generally followed, but introduced into medical literature by his teacher and colleague, Dr. Walshe. The book at once carried Reynolds to a position as leading authority on diseases of the nervous system, confirming him in the place left vacant by the death of his friend Marshall Ward. The full title of the book was "Epilepsy, its Symptoms and Relations to other Convulsive Diseases," and it was a picturesque, accurate, and forcible treatise upon all epileptiform conditions, far ahead of the general knowledge of the day, both revealing great acumen in the interpretation of obscure manifestations, and carrying the facts as far as their small amount would permit.

These treatises possessed the same qualities that we have noted as characteristic of Dr. Reynolds's verbal addresses—in fact, he imported into his lectures the precision of style and wide range of learning that he had cultivated in his writings. He was author first and lecturer afterwards. This may be seen in his Lectures on the Clinical Uses of Electricity, which appeared in 1871, and which are the only examples of his lectures which were ever printed for public circulation. At this date but little was known of electricity in its application to medicine or physiology. There were no electrical departments in connexion with the general hospitals, and the lectures, when they appeared were a revelation to the profession of the workings of what might almost without exaggeration be termed a new therapeutic agency. They presented the subject from the side of practical medicine, not from that of electrical science which has dominated some writers to an unpractical degree. But they would never have been printed had it not been that Dr. Reynolds's most assiduous and brilliant pupil at the time asked him one day when the course was completed why he did not publish his lectures on electricity, seeing that the subject was one on which the profession badly wanted instruction. Dr. Reynolds confessed that he shrank from the trouble because the lectures had been delivered from notes only and no real manuscript existed. "I can bring you the manuscript in the course of a few days," said the student (who was W. R. Gowers), "for I have taken down your lectures *verbatim* in shorthand as they were delivered."

In 1866 appeared the first volume of "A System of Medicine" under Dr. Russell Reynolds's editorship, and published by Messrs. Macmillan and Co. The science of surgery had some two or three years previously been summed up by the greatest British authorities under the superintendence of Mr. Holmes, and it was widely felt that a similar work on medicine was required; and it speaks very highly for Reynolds's reputation in the profession that at his age, and having been full physician to a general hospital for but one year, he should have been able to surround himself with a brilliant staff of representative medical authors. He discharged his own share splendidly. He wrote several admirable and lengthy articles; for instance, those on Erysipelas, Epilepsy, and Hysteria, but especially he excelled in his general introduction. This was the ablest summary of the existent conditions of medicine that had appeared. It dealt successively with the definition and nomenclature of disease, its natural history and diagnosis, therapeutics, and hygiene. The editor made no attempt to dogmatise. He laid down the principles on which a systematic treatise on medicine should be written with a happy union of philosophical acuteness and practical common sense. No one more thoroughly realised the insufficiency of the nomenclature of that day than did Reynolds, yet he furnished good reasons for compromise in the matter. Obvious mistakes must be corrected, but old associations must be respected. These were his extremes and he found the mean. In the passages devoted to the consideration of what is meant by symptoms of disease he rose to a very high level of philosophical discussion without for a moment losing his peculiar clearness of expression. It would be impossible to imagine a more beneficial corrective of loose style than the marshalling of his arguments; and as THE LANCET of that date said on the appearance of the first volume, "Many hard-worked medical men whose soul has often fainted within them when wandering in the howling wilderness of medical nosology welcomed with relief the simplicity of his scheme of classification." The "System of Medicine" took over ten years to complete, and the amount of trouble as well as literary labour that it entailed upon its editor was very great, in spite of the help he received, for the first three volumes, from the late Dr. Anstie, and for the last two from Dr. Gowers. He rightly allowed his staff free speech, but they took advantage of his genial administration and were unpunctual with their contributions and not careful to avoid the limitations in space laid down

Digitized by Google

for them. The great work suffered by the delay, as the sense of cohesion so perfectly suggested in the editorial foreword somewhat evaporated, while several repetitions crept in; but further exceptions to Reynolds's System have never been taken. It was a record of the science of medicine in its day, and many of its sections have been of permanent value to the profession; it was, in short, a great work, planned with boldness and due regard to order, and executed with thorough efficiency.

It is time to return to Dr. Reynolds's more purely professional career. Having proceeded to the degree of M.D. Lond. in 1852, he was elected a Fellow of University College in 1856 and a Fellow of the Royal College of Physicians of London in 1859. In 1868 he was appointed an Examiner in Medicine in London University for a period of five years, and in 1869 he was elected a Fellow of the Royal Society at the instance of his teacher, Professor Sharpey. At the Royal College of Physicians of London he was appointed Lumleian Lecturer in 1867, Censor in 1878, and Harveian Orator in 1884. The Lumleian Lectures and the Harveian Oration form a remarkable contrast in their style and in intention and illustrate well Reynolds's wide range of thought. The former had as their title "On Some Points in the Relation between Medical and Legal Practice," and were a good example of his simplicity and lucidity in dealing with matters of fact. The subject was one that interested him much (he returned to it later with a *brochure* entitled, "On the Scientific Value of the Legal Tests of Insanity," in which he dealt thoroughly and not very flatteringly with all the *criteria* of insanity upheld by the Courts), but he felt that it was one for assertion rather than speculation—one in which his task was to make things clear by the directest methods. The Harveian Oration, on the other hand, was a brilliant essay on the progress of medicine, full of original thought and beautiful simile, elaborate and eloquent, and terminating in a noble estimate of Harvey's character as a religious man, although an unfettered seeker after truth. It was a fine piece of high thinking expressed in appropriate words, but it was not absolutely simple reading.

In 1878 Dr. Russell Reynolds was appointed Physician to the Household, a post in which he earned the gratitude of many of Her Majesty's old servants as well as the esteem of his Sovereign; in 1884 he became consulting physician to University College Hospital; in 1890 he was appointed Senior Censor of the Royal College of Physicians of London; and in 1893 President of the College in succession to Sir Andrew Clark. In 1895 he was elected President of the British Medical Association, a post which he still held at his death, and in the same year he was created a Baronet. The present year brought further honours to him, for since its commencement the Universities of Edinburgh and Aberdeen have conferred upon him the honorary degree of LL.D. For his tenure of office as President no one had anything but words of warm praise. He was business-like, punctual, observant, and restful. The deliberations over which he presided took their tone from him, and it greatly facilitated official labour: he did not spare himself and made the wheels run smoothly for others.

Our readers are now in a position to estimate the loss that the death of Sir John Russell Reynolds will cause to the profession and the deep grief that is suffered by his devoted wife, his relations, and his large circle of affectionate friends. His life had been so busy that they and he alike were looking forward to the time when he should consider that the call of duty no longer precluded him from seeking a well-earned leisure. Not that for such as he freedom from the duties of office and the cares of practice would have meant idleness. Far from it. But it would have meant a period in which the time would have been his own to use as he chose—a form of leisure which it had not been his lot to enjoy for fifty years. That he would have turned aside now and again from medicine and pursued the arts of music and painting, in each of which he was an amateur of no mean proficiency, is probable, but the medical profession would also have benefited directly by a prolongation of his life. It was his intention to give to the world at the earliest possible date some of the results of his enormous practical experience in the form of a volume of scattered essays. He loved writing and was an artist in words. Therefore his literary output during his working life was, on the whole, small, for he required a certain aloofness from daily routine before he could make his pen serve faithfully its accurate, poetic, and fastidious master. The projected volume would have been largely a collection of addresses, speeches, and papers already published, but the additions would have transformed these into a new contribution to medicine, for it was Sir Russell Reynolds's design to write to each essay an appendix, bringing it up to date, and adding to it out of the carefully recorded experience of nearly half a century's assiduous practice in ward and consulting-room. That such a book would have had a deep and abiding interest for the profession we feel sure, but the bitterness of death interfering with the fulfilment of his design is not in this instance undiluted. Had Sir Russell Reynolds required such a monument to his memory it would have been sad that he should have died before its erection, but apart from his high official positions—indeed, decades before he reached them—he had earned for himself a secure position in medical history. His early writings were far in advance of any previous attempts to systematise the symptoms arising from nervous lesions. He appeared at a transition period, when order was just discernible forming itself out of chaos, and he was largely responsible for that order. Five or six years before the paths of microscopical investigation had been made plain by Lockhart Clarke, Reynolds was working at the clinical aspect of diseases of the nervous system and perfecting the knowledge and proving the surmises of Marshall Hall. Later a flood of light was to be thrown on these subjects by the philosophical lore, the research, and the clinical teachings of Hughlings Jackson, Bastian, Ferrier, Gowers, and Buzzard; but during the interval the torch was held aloft by Reynolds. He laboured at his subject, he interested as well as instructed others, he made things plain so that his successors could start with ease where he left off, and he rescued the manifestations of hysteria and epileptoid conditions from the curious uncanny kind of mystery in which they were shrouded and showed them to the whole profession as simple results of cause and effect. These are great accomplishments, and Reynolds, denuded of official and Court dignity, of his prestige as a writer, his reputation as a lecturer, and his claims upon the public as a general physician, would still remain secure of his fame as a pioneer in the science of medicine.

It was because of his early success as a neurologist and his abiding interest in the nervous phenomena of disease that the profession and the public alike decided that he should be a specialist; but a specialist he never was, and in its limited sense he repudiated the character very strongly, arguing that any success he might have achieved in particular walks was entirely due to the fact that his work had been thorough, comprehensive, and general. As has been said, one of the subjects in his "System of Medicine" on which he chose to write himself was Erysipelas, and as a clinical teacher he was every whit as effective and as instructive when discoursing on diseases of the lungs or of the heart or acute specific diseases as when dealing with the branch of medicine with which he was supposed to be most familiar. He carried his characteristic width of knowledge into all his work, and the practitioners who knew him best had equal reliance on his judgment in all classes of disease.

This sketch of the life of the great man just gone from among us would be incomplete without a brief presentation of his private character. Sir Russell Reynolds was a rigidly strict man in his code of honour, but full of kindness and sympathy. He was an exceedingly affectionate friend, but not at all a man of promiscuous friendships. High-minded, sensitive, and physically delicate, he shrank from the companionship of numerous persons to whom he was willing to be just, of whose merits he was appreciative, and whose interests he would take endless trouble to serve. But many of these he could no admit to intimacy, his standpoint in so many of the details of life being different from theirs. Studiously grave and quiet in his manner, those who did not know him well might have mistaken him for a melancholy man. And it would have been a mistake indeed, for all things, save a very few, he was ready to regard in a humorous light, while his conversation and his writings were full of witty allusion and quaint illustration, and he was never happier than when he found himself the cordial host to a group of congenial friends.

For religious effort of thought or deed he had the sincerest respect. A friend (not of the medical profession) who has known him intimately for more than the last thirty years has written to us thus concerning him, and it would be impossible to improve upon this estimate of Sir Russell Reynolds:—"Of all the men

Digitized by Google

whom I have seen with their armour on or off he will ever live in my memory as most keenly sympathetic. Nothing personal put him out, and yet this came from no apathy of temperament, for he was quick in responding to every phase of life, but from sheer power of apprehension and ability to see in a glance that something could always be said on both sides in a crisis which other men might take time to disentangle and so be drawn into hasty or complacent utterance. Though eminently tolerant and tender-hearted, Dr. Reynolds was not a man to make things pleasant or speak smoothly when he smelt dishonour, duplicity, or injustice, for he had no respect of persons and delivered his mind when occasion arose with unmistakable distinctness. He was, moreover, thoughtfully unselfish, putting himself, for instance, to continuous trouble in a case of the most commonplace suffering if he thought he might be able to mitigate it. And when a friend was ill, though not necessarily a patient, his loving tenderness was enough to make the sufferer think that Reynolds had no other claim upon him or drain upon his time. And he was as generous with his purse as with his power, and wise though free in his charity. There is no need of many words to record the manifold hospitality shown by Lady Reynolds and himself, but it was, perhaps, at the gathering of a few friends that the charm and flavour of it came to be most shed and felt, for though he could speak and preside with gracious effect he did not exult, as some do, in the semi-public performances of a host. It was in the warm social atmosphere of his own house that his geniality unfolded itself. And this was backed by what many learned and wise souls are without—i.e., the keenest sense of humour and ability to discern between the ridiculous and the witty in man and his ways."

His old friend goes on to say: "In setting sadly down a few of the things which crowd my memory while thinking of the sorrow now fallen upon his family and so many beside myself, those who knew him best feel it to be mitigated by the remembrance of the high motives which were plainly behind all that he said and did. They know, moreover, that his incisive scientific perception was associated with a profound sense of those hidden laws of life which elude analysis, but cannot be disregarded by genuinely intellectual minds. He was moved and strengthened by the deepest Christian faith, of which he made no reproachful display, though he never shrank from openly claiming it as a true support of his life and work, being a devout worshipper and communicant at his chosen church."

We hope that we have drawn Sir John Russell Reynolds with sufficient distinctness for our readers to recognise what manner of man it was whose remains were quietly laid to rest in the little Gloucestershire churchyard on Tuesday last. It only remains to add a few words concerning his last illness. During the whole of last year he was undoubtedly overworked. He suffered severely from influenza in March of that year, while he was prevented through his numerous engagements, official and private, from securing a proper holiday. Though with somewhat of a struggle, he succeeded in discharging conscientiously his double duties as President of the Royal College of Physicians of London and of the British Medical Association, and left London in the autumn. In November he again fell a victim to influenza, but returned to his work before Christmas. He was undoubtedly not quite himself at the end of the year: he had not recovered strength or tone and was occasionally very weak in his movements. At the beginning of 1896 he went to Hastings, and returned somewhat stronger and feeling himself more apt for work. But the improvement was of short duration, the physical weakness increased, and at the advice of his friends he decided not to offer himself for re-election in April as President of the Royal College of Physicians of London. Again he left London, and again returned feeling better, so much better, indeed, that on the day of his return he saw patients and made appointments to see others. But that afternoon, most unfortunately, on returning from a drive he slipped on his own doorstep and bruised his ankle severely. The injury was sufficient to compel him to keep his bed, and from that time he went steadily down, slowly at first, but at the end rapidly. Until the last week or so of his illness he preserved his faculties, but the intellectual capacity was badly served by the extreme physical failure. On Friday last (May 29th) he died peacefully and painlessly without a struggle in the presence of his devoted wife, who never left him for a moment during his long illness. To her we tender our sincere and respectful sympathy, feeling sure that it must be a consolation to her even now when her sorrow is keenest and greenest to know that her husband's memory will be preserved with unstinted honour in the hearts of the profession that he adorned and served so well.

CHOLERA IN EGYPT.

As regards the progress of this disease in Egypt the returns for the week ending May 30th show that there were 111 cases and 93 deaths at Alexandria and 286 cases with 243 deaths at Cairo. At Tourah there were 119 cases and 80 deaths. With regard to the disease in the provinces and outlying districts and villages the statistics are scanty and unreliable, but there does not seem to be any doubt that the epidemic is slowly but surely extending itself, in Lower Egypt especially. A fatal case has occurred among the British troops quartered at the citadel in Cairo, but as it was an isolated case and the soldier occupied a detached building it was not deemed necessary to evacuate the barracks. The latest returns show that the number of cases at Alexandria and Cairo is declining. Five deaths from cholera occurred at Alexandria on the 1st inst., and 35 in Cairo. There are at present in Cairo about 162 cases altogether. Since last September over 3000 cases have occurred, with a mortality of over 2500. The Egyptian Government has, it is understood, requested the Pasteur Institute to send a mission to Cairo to make experiments with a new anti-cholera serum. The authorities in Egypt have had many warnings of late to set their house in order and prepare for an outbreak of epidemic disease by the introduction of some scheme for the water-supply and drainage of its larger cities and towns and the organisation of sanitary measures generally, but the complicated nature of the government of the country and its opposing factions, the cost of carrying out sanitary engineering works—to say nothing of what particular scheme should be adopted—and the opposition that all sanitary measures and precautions have to encounter have hitherto prevented any adequate action in this respect. The disease (cholera) was there; it was only dormant and ready to manifest itself afresh on favouring climatic conditions. The high death-rate among the native population, and especially among the children, that occurs year after year also affords a sufficient indication of the state of public health and hygiene in Egypt. The adoption of sanitary measures when an epidemic is actually present is always most difficult and frequently futile, while their enforcement often provokes great opposition and mob riots among an ignorant and fanatical population, as has been the case at Cairo on the present occasion. However, we can only repeat now what we have so often urged already in connexion with this subject. There is no royal road and short cut to dealing effectively with epidemics. Once they have begun the stamping-out process among mixed populations is by no means so simple as people imagine. The lesson that experience enforces on us is, that the way to stamp out epidemics is by removing the soil in which they grow by precautionary sanitary measures adopted in advance of their occurrence. Meanwhile the sanitary authorities in Egypt have to deal with the facts confronting them as best they can, and it must in justice be said that they seem to be acting with energy and good judgment.

While there is no doubt about the nature of the disease prevalent in Egypt, there appears to be considerable doubt as to the presence of epidemic cholera in Spain, where a cholera scare has nevertheless arisen. There have been a few suspicious cases at Toledo and a large number at Carpio, in the same province, but as the disease has so far not been attended with fatal results it is scarcely likely to be true cholera; indeed, the outbreak has been locally attributed to bad milk.

When writing a memorandum in January last on the recent outbreak of cholera in Egypt, Dr. Rogers Pasha, C.M.G., D.S.O., the head of the sanitary department, said, "Whether the disease will be entirely stamped out before the summer, I cannot say," and Lord Cromer also made a similar reservation in his report. For some months it appeared as if these precautionary utterances were superfluous, for from the week ending Feb. 4th, as will be seen by the subjoined table compiled from the official *Bulletins Hebdomadaires*, the epidemic seemed to be entirely extinguished

Digitized by Google

throughout the country, save for occasional sporadic cases at Alexandria, where it might *a priori* be supposed that they could be most effectually dealt with:—

Week ending 1896.	Place.	Government ambulances.					Deaths from cholera outside ambulances.

Towards the end of April, however, a fatal case was reported from Assiout in Middle Egypt, and the following week the Delta was found to be once more contaminated in three distinct centres. Since then the resurgent epidemic has made alarming progress, the chief places attacked being Alexandria, Cairo, old Cairo, and Tourah, and unfortunately the expectant attitude assumed by Dr. Rogers Pasha is only too completely justified.

It is a remarkable thing that for close on three months cholera should have remained smouldering in Alexandria while elsewhere the disease was apparently stamped out. Alexandria is supposed to be the most advanced town in Egypt with regard to civilisation. It contains many splendid buildings, well lighted and paved streets, and boasts of an efficient scavenging service. Its internal affairs are administered by a municipality in which the European element largely predominates, and there should be no lack of money to place the great seaport above reproach from a sanitary point of view. Alexandria is also the only town in the country which possesses sewers, but unfortunately it is a question whether these subterranean channels are not a source of more harm than good. Built in piecemeal fashion on the massive culvert plan they do not possess sufficient fall, or anything like it, and the house connexions, as a rule, permit the freest reflux of noxious gases. Even in the newest and most palatial edifices the drainage of the block is effected through uncemented shafts left in the thickness of the wall during the process of building. These unlined shoots permit the oozing out of the fluid contents and hence the unsightly patches defacing the rear, and in some cases the façade of the imposing-looking structures. The privy accommodation is of the most primitive description, consisting of a marble slab with a hole in the centre. It is invariably situated next the kitchen or even in the same apartment with merely a screen between it and the stove. When a medical man visits a patient and wishes to ascertain the state of his bowels the stock inquiry is, "Have you been to the kitchen to-day?"

In this connexion the following extract from a report by Sir E. Baring (now Lord Cromer), which was presented to the British Parliament in 1891, will be read with interest:—"I have already spoken of sanitation in dealing with the medical department. I will here only add that an attempt was made some years ago to introduce something like order into the sewerage system of Alexandria; it had to be abandoned, as it was found impossible to carry it into execution without infringing the legal rights of the European residents. It is especially in matters of this sort that the rights conferred by the Capitulations hamper well-intentioned efforts at reform, and act in a manner which is in reality detrimental to the true interests of Europeans and natives alike."

It will readily be understood how terribly handicapped the sanitary officials must have found themselves whilst endeavouring to dislodge their enemy from his ultimate stronghold, and truly it is no wonder that under the circumstances they were unsuccessful. After lingering in Alexandria for nearly three months the epidemic has burst forth with renewed virulence, and all the work of repression has to be recommenced. Sisyphean labour of this description is unquestionably discouraging, but there is not, of course, the least reason to dread the slighest relaxation of effort in the case of the Englishmen employed in the sanitary department. The European members of the Alexandria municipality are said to have fled from their posts, frightened out of all sense of duty and decency by the death from cholera of a well-known lady. As long as the victims were natives of the lower classes no one seemed to care very much, but no sooner did the disease attack a European than, as on former occasions, panic at once set in.

PUBLIC HEALTH IN MASSACHUSETTS DURING 1894.

THE twenty-sixth annual report of the State Board of Health of Massachusetts is well worthy of the series to which it belongs, and this is no faint praise. For many years past these volumes have ranked with the very first of public health literature, and the work which the Board have done and are doing, more especially in experimental directions, entitles them to the gratitude of all workers in sanitary science. To attempt a review of a volume containing some 1000 pages in the space at our disposal is obviously futile, but we may, by giving some indication of its more important contents, serve to guide those interested in the subject of which it treats to the valuable matter it contains. On the subject of small-pox and vaccination there is much of interest, and in these days it is as well to cull statistics from foreign as well as from home sources. From 1885–94 the fatality-rate from small-pox among the vaccinated was 5·5 per cent. as compared with 29·1 among the unvaccinated, and 27·4 among the unknown. For the years 1888–94 the details with regard to age distribution are given, and these show that: (1) no vaccinated child under one year was attacked with small-pox, as against 17 among the unvaccinated, and of these latter 9, or 53 per cent., died; (2) among vaccinated persons under fifteen years of age there were 18 attacks and no deaths; (3) among vaccinated adults there were 109 attacks and 8 deaths, or 7·3 per cent.; (4) among unvaccinated adults there were 66 attacks and 21 deaths, or 31·8 per cent.; and (5) all the deaths of the vaccinated were among adults, while nearly 42 per cent. of the deaths of the unvaccinated occurred among children.

The report contains an interesting summary of statistics of several states and countries for the twenty years 1871–1890, and as regards a comparison of Massachusetts with England and Wales, the marriage-, birth-, and death-rates of the former were 18·1, 25·7, and 19·7 respectively, while for the latter they were 15·6, 34·0, and 20·3. The statistical aspect of the report under consideration is very fully developed, and it will repay perusal by all those who are interested in comparing the statistics of the several infectious diseases in the old and new world. In this part of the report there may be mentioned a curve which shows that since 1853 there has been a steady decrease in the mortality from phthisis in Massachusetts, the rate per 10,000 being 41·1 for the five-yearly period 1851–55 and but 23·6 for the period 1891–93. The mortality from phthisis in the dense districts being taken as 1000, that in the medium districts is found to be 810, and that in the sparse districts as 727. It seems, too, that the mortality from phthisis in Massachusetts diminishes in its ratio to the distance from the sea-coast.

The water-supply of Boston is the subject of a special report, and in it the Board state that they have taken as the assumption upon which to work the estimate that the

Digitized by Google

growth of Boston and the district surrounding it will continue at the same rate as it has done during the last twenty-five years. It is proposed to form a Metropolitan Water District containing a population of some 848,000. The Board report that they have found a thoroughly satisfactory supply for the district in question in the south branch of the Nashua River above the town of Clinton, and they point out that should further supplies be needed at a future date they can be easily procured. A considerable portion of the Massachusetts report is taken up as usual with the advice given by the Board to cities or towns which are about to establish works of water-supply or sewerage. It is one of the statutory duties of the Board to from time to time consult with and advise authorities, and in the execution of these duties much valuable experimental work is conducted by the Board. For instance, even in the ordinary routine work of the year there have been no fewer than 2006 samples of water examined chemically and microscopically, while much has also been done in the connexion between the odour and taste of waters and the organisms contained in them. Dr. Thomas Drown, the chemist to the Board, has done good work with regard to the composition of deep well waters in Boston and its vicinity, whilst Dr. Sedgewick, the Board's biologist, and Mr. Prescott, S.B., have contributed a valuable and useful paper on the bacteria contained in certain ground waters, including deep wells, in which they have demonstrated that these waters are by no means as free from bacteria as has generally been supposed. The writers show that even deep tubular well waters are not free from bacteria, and they promise in a subsequent paper a report upon the probable source of the bacteria and the species present. It seems, however, that but few liquefying colonies presented themselves and that there was an abundance of chromogenic organisms, facts which, as they point out, tend to strengthen faith in waters of this description. Many of our readers are probably familiar with the extremely valuable work done by the Massachusetts Board in connexion with the purification of sewage and water at the Lawrence Experimental Station, and they will be glad to hear that these experiments have been continued during 1894 and that the results are set forth in the volume under review. It can only here be stated that the experiments include investigations upon the composition of sewage, of the effects of precipitation and sedimentation upon bacterial purity, and of the influence of sewage composition and of temperature upon nitrification. The effects as regards water filtration of using coarser filters at high rates of filtration and the bacterial effects of such treatment have been gone into, and there is also a valuable paper by Mr. Clarke on the physical and chemical properties of sand in relation to the filtering of water.

THE MAUSER RIFLE IN THE CUBAN WAR.

DR. ENRIQUE PEDRAZA, a Spanish military surgeon, contributes to the *Revista de Ciencias Médicas* of Havanna an interesting article on the effects of the Mauser projectile as seen by him in the present war. He points out the great difference which exists between this and the older forms of projectile as the Remington and Freire Brul. These latter being much larger and having a smaller initial velocity cause large openings and carry septic materials into the wounds they make which are therefore very difficult to render aseptic on the field and consequently when they come under proper treatment in a hospital are in a condition which is very difficult to manage, especially when, as is frequently the case, the hæmorrhage has necessitated the use of perchloride of iron which increases the size of the wound or when a bone has been hit, and, as usually happens, even at distances of 100 or 150 yards, is shattered.

The Mauser projectile as issued in the Spanish Army is 3 centimetres in length and 7 millimetres in diameter, and consists of a hard nucleus of lead and antimony coated with steel, outside which is a coating of nickel and copper alloy, the whole weighing 13·7 grammes and having an initial velocity of 632 metres per second, which enables it to pierce a Krupp steel plate 10·5 millimetres in thickness at a distance of 50 metres. Such a projectile ought, it might be thought, to produce a clean and minute wound with little hæmorrhage, easy to close on the field and therefore likely to heal rapidly in hospital, more especially as the bones would be bored rather than shattered and as there would be little chance of foreign matter being introduced into the wound by the projectile itself. These expectations are, however, by no means always realised, and the first few cases of primary wounds from a Mauser projectile which Dr. Pedraza saw at Manzanillo very greatly surprised and disappointed him. With longer experience, however, he learned that the benign results he had expected to see do occur, but only when the enemy is 150 yards or more distant. When the patient is shot at from 10 to 70 yards the destruction of the tissues is very great, and it is this that has given rise to the suspicion that explosive bullets were being used, especially as the orifices of entrance and outlet are sometimes so small that they can scarcely be seen. The explanation suggested is that the shock which the enormous velocity of the projectile produces on entering the soft parts causes them to behave as a fluid or semi-fluid does when enclosed in a box and "shot through," the hydraulic pressure bursting the sides, or, if an opening be left, driving a column of the fluid through it. As to how far any destruction of the projectile itself may be a contributing factor he has no direct evidence, but from specimens he has seen of the Wagner and Mannlicher projectiles after experiments made by Dr. Cardenal, which he showed at a lecture before the Cataluna Academy of Medicine, he thinks it probable that the projectiles do become more or less disintegrated when they hit at short distances.

In striking contrast to such wounds are those produced at 150 yards or more by the Mauser rifle. Here the entrance and outlet are very small and there is but little evidence of internal destruction, even bones being tunnelled through without fracture, and as aseptic treatment is possible from the first a rapid recovery may usually be anticipated. Thus, in one case where the projectile entered the abdomen in the eighth intercostal space on the right side, passing through the stomach, and coming out three fingers' breadth on the left of the sternum, though the ninth rib was fractured and the patient suffered from vomiting, hæmatemesis, and fever, he very soon improved and recovered completely. In another case the projectile entered the left frontal eminence, passing out by the right parotid region. The patient suffered from concussion of the brain, ecchymosis of both the right eyelids, with some difficulty of vision of that eye, but recovered in twenty-six days. If, therefore, it could be arranged that fighting should never occur at less than 200 yards distance the Mauser would, Dr. Pedraza thinks, be a most humane weapon.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England was held on the 18th ult. at 25, Grosvenor-street, W., Mr. T. Holmes, Vice-President, being in the chair.

Mr. Percy Dunn, honorary secretary, reported that he had received a reply from the President, forwarded through the Secretary to the College, to the resolution passed at the meeting of the Committee on May 6th. The reply was to the effect that it had appeared to the President that the Committee had misinterpreted or had been misinformed as to the proceedings of the Council at the meeting in February, as no such agreement as that referred to in the resolution had been arrived at by the Council either at the meeting in February or at any subsequent meeting. It was decided that no action should be taken regarding this communication. With regard to the resolution of the Council of the College in favour of polling the Fellows on the question of the representation of the Members on the Council the following resolution was unanimously adopted:—"The Committee of the Association of Fellows, understanding that the Council of the College of Surgeons have nominated a Committee for the purpose of ascertaining the opinion of the Fellows on the question of the Members' representation on the Council, respectfully suggest the following as the points which should be submitted to each Fellow: 1. Are you in favour of giving to the Members direct representation on the Council? 2. If so, do you think

Digitized by Google

that such representatives should be Fellows only, or would you accept Members as representatives? 3. What number of such representatives would you admit? 4. Should they be in addition to the present Council?" A copy of this resolution was directed to be sent to the Secretary of the College with the request that it be laid before the Council at the next meeting.

It was also reported that the vacancies on the Council this year would be caused by the retirement of Mr. Cadge, Mr. Bryant, and Mr. Pick. It was understood that Mr. Cadge did not intend to offer himself for re-election, but that Mr. Bryant and Mr. Pick would again come forward. It was pointed out that Mr. Bryant had already served two consecutive periods of eight years each and had passed the chair and that the Association had advocated the ineligibility of Councillors for re-election after they had served two full periods of eight years. The results of such re-elections had not been at all satisfactory. The honorary secretary was instructed to communicate with Mr. Victor Horsley with a view to ascertain his intention as to becoming a candidate for the Council in July next. A similar instruction was given with respect to a provincial Fellow. A long discussion then followed regarding the action which it would be expedient for the Association to take in the event of certain other candidates coming forward. Ultimately the discussion was adjourned until the next meeting of the Committee.

THE TREATMENT OF HABITUAL DRUNKARDS AND THE "CURATEL" PROCEDURE.

A MOST interesting report on "The Treatment of Habitual Drunkards in Austria and the 'Curatel' Procedure" has just been issued by the Foreign Office in its "Miscellaneous Series." From this report it would appear that very little legislation on the subject of drink and drunkards has actually taken place in Austria, drunkards only coming under the law in that country as "spendthrifts" or "idiots." The process of "Curatel," whereby the court appoints a curator or administrator for persons who do not look after their own affairs and who are unable to defend their rights, is made applicable not only to children, lunatics, and idiots, but also to those who, having been declared "spendthrifts" by a magistrate, have been deprived of the administration of their property. A man may be judicially termed a "spendthrift" if it appears on examination of the charge that he is running through his property in a senseless way and that he is exposing his family to future destitution by contracting loans under reckless or ruinous conditions.

In some kingdoms, as in Galicia and Lodomeria, there is a special law for the prevention of drunkenness, and one section provides that on being convicted of drunkenness three times in the course of one year, the district authorities may forbid the offender to visit public-houses or liquor shops in the neighbourhood of his domicile for the period of one year, under pain of fine or imprisonment. The inadvisability of mixing mere drunkards with the insane in asylums is fully recognised by the Austrian authorities. Last year a Bill for the erection of public asylums or establishments for the cure and reform of drunkards was brought into the Reichsrath by the Ministry of Justice. These institutions are intended for the reception of (1) those who have been judicially punished for drunkenness three times in the course of one year; (2) those mentally affected owing to habitual or periodical abuse of alcohol who have been admitted into hospitals or lunatic asylums and who, although they have recovered their sanity, have not sufficient self-command to resist the temptation to drink; and (3) those who, owing to habitual or periodical abuse of alcohol, endanger the moral, physical, or financial security of themselves or their relations. Provision is also made for the compulsory retention of patients for a period which may not exceed two years and placing the police and judicial authorities at the disposal of the administration of the asylum in order to recover fugitives from the same. Consideration is given to the proper safeguarding of the individual from the illegal and undue application of the various processes upon which detention in an asylum may be carried out.

The provisions of the Bill are worked out very much upon the lines and recommendations of the Home Office Departmental Committee which sat in 1891-92, and we hope that with a judicious and firm application of the "Curatel" procedure not only will the unfortunate victims of this sad propensity hail the results with gratification, but the public also will be constrained to withdraw their dread "bogey" of "interference with the liberty of the subject" when they see what an influence for good the new procedure shows itself to be. After all, what sort of "liberty" is sottishness, and what sort of a "subject" is the habitual and reckless drunkard.

Voluntary inmates of these institutions for drunkards are to be on the same footing as those who are compulsorily placed in them.

THE MIDDLESEX HOSPITAL.

THE quarterly general Court of Governors of the Middlesex Hospital was held on May 28th, Mr. T. W. Nunn, F.R.C.S., in the chair. Among those present were the Right Hon. Sir R. Thompson, K.C.B. (chairman of the weekly board), Sir A. T. Watson, Bart., Mr. F. Hoare, Lieutenant-Colonel T. Lambert Mears, Mr. J. G. Noel, C.B., and others. The report of the weekly board states that the building of the convalescent home at Clacton-on-Sea is progressing satisfactorily and that the home will be ready for occupation in July. A *fête* in celebration of this event will take place in the grounds of the hospital on July 1st and will be inaugurated by their Royal Highnesses the Duke and Duchess of York. It is estimated that the total cost of the convalescent home will be nearly £30,000, of which amount about two-thirds has already been paid from funds at the disposal of the Samaritan Fund, aided by an advance of £16.000 from the Spicer trustees on mortgage, and a loan of £2000 from the bankers. Allusion is made to the losses sustained by the hospital in the deaths of Baron de Hirsch, vice-president, and Mr. W. Debenham, for nineteen years a member of the board. To Mr. Debenham the credit of establishing the convalescent home must be in great measure attributed. The Right Hon. Viscount Gort has been elected vice-president, and Mr. F. Debenham has accepted the vacant seat on the board. The retirement of Mr. George Lawson from the active staff, after a service of thirty-three years, is announced, and his appointment as consulting surgeon recommended to the Court. Mr. Pearce Gould has been elected to the vacant office of surgeon. An important paragraph of the report bears on medical education. It states that "the Board are proceeding with the negotiations for the amalgamation of the hospital and medical school, and as soon as a report has been received from the subcommittee appointed to consider the financial clauses the board anticipate that they will be in a position to submit a scheme in a complete form for consideration by the Court of Governors." Dr. Arthur Robinson, late of Owens College, has been appointed lecturer on anatomy, and Dr. R. A. Young lecturer on physiology. The plans of the new cancer wing have been approved. After reference to other matters the report closes with a statement to the effect that during the quarter ending March 31st 487 medical and 599 surgical patients were treated in the hospital, 77 had died and 302 remained in hospital on April 1st. During the same period 10,477 patients were treated in the out-patient department, the total number of attendances giving an average of 305 patients seen daily.

CONTRIBUTIONS TO THE NEW PHOTOGRAPHY.

WE continue to receive from week to week communications on subjects illustrating the value of the "X" rays in surgical diagnosis. In the main, however, the applications appear to be restricted to the examination of hands and limbs and no practical success appears yet to have attended the exploration of deeper parts, save in the work of Mr. William Turner, the Surgical Registrar of King's College, London. This gentleman has made some very interesting radiographs of joints and of the processes of union after

Digitized by Google

fracture among other things, and we shall publish his paper upon them shortly—next week if possible.

The General Electric Company of Berlin have effected an improvement in the Roentgen apparatus, so that it is now possible to observe peculiarities in the interior of the head and throat and especially the action of the lungs and heart by direct inspection with the fluorescent screen. This improvement is to be submitted for inspection to the Twenty-fifth Surgical Congress now sitting at Berlin, when Dr. Virchow, Sir Spencer Wells, Dr. Guyon of Paris, Dr. Ollier of Lyons, Dr. Antona of Naples, and Dr. Lange of New York are expected to be present.

Mr. F. C. Abbott has sent to us one of the best examples of the new photography applied to surgery that we have as yet seen. It is a photograph of a backward dislocation of the right elbow of a woman. Eight weeks before admission to St. Thomas's Hospital she injured the right elbow by direct violence. Her medical man at that time diagnosed fracture of the humerus and put the arm in splints. The arm subsequently swelled greatly and was treated at an infirmary by the application of an icebag. On admission to St. Thomas's Hospital, under the care of Mr. Bernard Pitts, the right elbow was found to be considerably swollen and thickened, the forearm was semi-flexed, and there was great limitation of movement. The diagnosis rested between fracture of the lower end of the humerus with backward displacement and a backward dislocation of the forearm, and at first presented some difficulty owing to the swelling. The photograph, which was taken by Messrs. White and Stanley Kent, at once made the diagnosis plain, the displacement of the humerus being shown with admirable clearness.

Mr. Basil Trevelyan sends us a successful photograph of the left hand of a patient who accidentally shot himself in the palm with a pistol. The photograph shows clearly the position of the bullet, although most careful exploration under an anæsthetic had failed to discover it. On cutting down at the place indicated in the photograph Mr. Trevelyan successfully extracted the bullet which was found to be resting upon the internal lateral ligament of the wrist-joint. The bullet had evidently glanced against the middle metacarpal bone and so was directed upwards and inwards for a distance of over three inches.

Mr. C. Coppinger sends us some photographs which are of interest because they were taken directly on prepared sensitive paper, and hence the bones appear white and not black as in most photographs hitherto taken. He does not, however, give details of the process as to the time of the exposure or as to the kind of paper used. He also encloses a print of a case of tuberculous dactylitis.

A NURSING EXHIBITION.

THE idea of a nursing exhibition was a happy one, and Mrs. Bedford Fenwick, the editor of the *Nursing Record*, and those who have assisted her, are to be congratulated on the organisation of the exhibition, which opened at St. Martin's Town Hall, Charing-cross, on Monday last. Nursing as a profession is growing every year, and appliances for the care and comfort of the sick are daily increasing, but it is only the metropolitan nurse who has an opportunity of keeping pace with this increase, and her sister in the country knows little or nothing of the progress that is being made. In this exhibition the latest and most approved appliances for the comfort and welfare of the sick and injured are brought together and are likely to prove of great educational value to the nurse as well as to the general public.

One of the first things which will be noticed by the visitor is the effigy of a nurse on a Humber bicycle. This is exhibited by Messrs. Debenham and Freebody of Wigmore-street, Cavendish-square, by request, in order to show a special form of cloak for the use of district nurses who use the cycle in place of the somewhat expensive dogcart. Many of the exhibits are brilliant testimonials to the industry of the hospital nurses of the metropolis, who, amidst their arduous duties, have found time to construct models which exhibit in a very striking way the practical application of many of the appliances. Literature is represented by a selection of Messrs. Cassell and Co.'s publications relating to nursing and invalid cookery. Messrs. Maw, Son, and Thompson's exhibit of aseptic instrument cases occupies a prominent position in the large hall, and Messrs. Burroughs Wellcome & Co. have a notable display. Disinfectants and deodorisers are represented by Sanitas and the new non-poisonous "Electrozone," made from sea-water by electricity, the Arema Manufacturing Company, and the Red Cross Germicide Company.

The Frame Food Company have an interesting exhibit of their preparations, and visitors with a predilection for tasting can exercise their propensity both at this stall and that of Messrs. Stephen Smith and Co. of Bow, who dispense Hall's coca wine, and a new preparation of Liebig's extract of meat with malt wine. Messrs. Reynolds and Branson, Messrs. W. H. Bailey and Son, Messrs. Southall Brothers and Barclay, Messrs. Down Brothers, and Mr. J. H. Montague of New Bond-street have some useful appliances on view, and Messrs. Edward Cook and Company have a large exhibit of their toilet preparations. The Bovril Co., Messrs. Welford and Sons with their stand of sterilised and peptonised milks and Messrs. Cadbury Brothers are also represented. The Gorham Patent Bedstead Company, Ltd., give practical demonstrations of their ingenious invention and the Bed Support Company have on view their "Excelsior" bed supports. During the progress of the exhibition, which will remain open till June 13th, many popular vocalists and instrumentalists will appear; a conference of nurses will also take place and papers of interest to the nursing profession will be read.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5609 births and 3668 deaths were registered during the week ending May 30th. The annual rate of mortality in these towns, which had declined in the three preceding weeks from 18·5 to 18·1 per 1000, further fell last week to 17·6. In London the rate was 16·9 per 1000, while it averaged 18·2 in the thirty-two provincial towns. The lowest rates in these towns were 8·5 in Swansea, 12·3 in Leicester, 12·8 in Derby, 13·0 in Norwich, and 14·2 in Bristol; the highest rates were 20·7 in Liverpool, 20·8 in Hull, 21·8 in Oldham, 23·0 in Sheffield, and 24·1 in Sunderland. The 3668 deaths included 542 which were referred to the principal zymotic diseases, against 562 and 591 in the two preceding weeks; of these, 195 resulted from measles, 151 from whooping-cough, 67 from diphtheria, 54 from diarrhœa, 48 from scarlet fever, 27 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases was recorded in Brighton, in Blackburn, or in Halifax; in the other towns they caused the lowest death-rates in Swansea, Derby, and Bradford, and the highest rates in West Ham, Salford, Oldham, Hull, and Croydon. The greatest mortality from measles occurred in Huddersfield, Croydon, Manchester, Sunderland, Hull, and Oldham; from scarlet fever in Bristol and Salford; from whooping-cough in Croydon, Cardiff, Bolton, West Ham, Preston, and Salford; and from diarrhœa in Hull and Plymouth. The mortality from "fever" showed no marked excess in any of the large towns. The 67 deaths from diphtheria included 40 in London, 4 in West Ham, 4 in Birmingham, and 4 in Liverpool. No fatal case of small-pox was registered last week in any of the thirty-three large towns. There were 19 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, May 30th, against 15, 20, and 22 at the end of the three preceding weeks; 3 new cases were admitted during the week, against 5, 6, and 5 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2679, against 2527, 2539, and 2596 on the three preceding Saturdays; 297 new cases were admitted during the week, against 238, 293, and 305 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the four preceding weeks 292 to 217, rose again last week to 230, but were 44 below the corrected average. The causes of 47, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Bradford, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of

Digitized by Google

uncertified deaths were registered in Nottingham, Blackburn, Preston, and Hull.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 19·3 and 19·2 per 1000 in the two preceding weeks, was again 19·2 last week, and was 1·6 per 1000 bove the mean rate during the same period in the hirty-three large English towns. The rates in the eight Scotch towns ranged from 14 3 in Greenock and 15·2 in Edinburgh to 22·5 in Dundee and 27·4 in Perth. The 560 deaths in these towns included 27 which were referred to whooping-cough, 20 to measles, 17 to diarrhœa, 10 to "fever" (principally enteric), 6 to scarlet fever, and 3 to diphtheria. In all, 83 deaths resulted from these principal zymotic diseases, against 72 and 82 in the two preceding weeks. These 83 deaths were equal to an annual rate of 2·8 per 1000, which was slightly above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 38 and 29 in the two preceding weeks, further declined to 27 last week, of which 17 occurred in Glasgow, 4 in Edinburgh, 3 in Aberdeen, and 3 in Paisley. The 20 deaths from measles, were within one of the number in the preceding week, and included 19 in Glasgow. The deaths referred to different forms of "fever," which had been 4 and 6 in the two preceding weeks, further rose to 10 last week, of which 6 occurred in Glasgow, and 2 in Edinburgh. The fatal cases of scarlet fever, which had been 3 and 5 in the two preceeding weeks, further rose to 6 last week, and included 2 in Edinburgh and 2 Greenock. The 3 deaths from diphtheria corresponded with the number in the preceding week, and included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 92 and 109 in the two preceding weeks, declined again to 97 last week, and were 21 below the number in the corresponding week of last year. The causes of 33, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the three preceding weeks from 21·9 to 23 7 per 1000, further rose to 23·9 during the week ending May 30th. During the past nine weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 18·4 in London and 17·4 in Edinburgh. The 160 deaths registered in Dublin during the week under notice were within 1 of the number in the preceding week, and included 9 which were referred to the principal zymotic diseases, against 5 and 9 in the two preceding weeks; of these, 5 resulted from "fever," 3 from diarrhœa, and 1 from scarlet fever, and not 1 either from small-pox, measles, diphtheria, or whooping-cough. These 9 deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 3·0 in London and 2·3 in Edinburgh. The 5 deaths referred to different forms of "fever" exceeded by 2 the number recorded in the preceding week. The 3 fatal cases of diarrhœa exceeded the number in any recent week, while the mortality from scarlet fever corresponded with that recorded in the preceding week. The 160 deaths in Dublin last week included 26 of infants under one year of age, and 40 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded the numbers returned in the preceding week. Four inquest cases and 4 deaths from violence were registered; and 53, or nearly a third, of the deaths occurred in public institutions. The causes of 15, or more than 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL MILITARY TOURNAMENT.

THAT the Royal Military Tournament, under what is practically new management, is a success the announcement which was posted up in the Royal Agricultural Hall on Tuesday afternoon last fully testifies: "House full; every seat sold"; and in spite of the fact that Wednesday was Derby Day the Hall filled at both afternoon and evening performances. It is to be noted, too, that since the opening on Thursday, May 28th, the number of visitors exceeded those who visited the tournament on corresponding days last year. We, therefore, offer our congratulations to the members of the executive committee—Major-General Lord Methuen, C.B., C.M.G. (chairman) Colonel W. H. Mackinnon, A.A.G. (vice-chairman) Lieutenant-Colonel R. S. S. Baden-Powell, 13th Hussars; Major J. S. S. Barker, R.A.; Major Irvine, R.E.; Captain Bramhall, A.S.C.; Colonel E. Villiers, 1st Surrey Rifles; Colonel G. M. Fox (commandant); Lieutenant-Colonel E. Blaksley, R.H.A.; Lieutenant-Colonel E. W. D. Ward, C.B., D.A.A.G. (hon. treasurer); and to Major Eyre Crabbe, Grenadier Guards (hon. secretary)—on whom the responsibility for the excellent management mainly rests. It is also gratifying to know that under the presidency of the new Commander-in-Chief, Lord Wolseley, the proceeds of the tournament, which bid fair to be unprecedented, will this year be distributed among all the military charities and not given to one institution as hitherto, and that the naval charities will also receive a share. The object of the seventeenth Royal Military Tournament, as set forth in the general rules, is "to encourage and develop skill at arms in all ranks of Her Majesty's Regular and Auxiliary Forces and to benefit various military charities"; but incidentally it must be a powerful factor in popularising the various departments of the Services as well as in promoting true patriotic pride. This is particularly shown in the bursts of applause which usher into the arena each detachment which takes part in the brilliant pageant "Sons of the Empire." In this display it has been the endeavour of the committee to give some idea to the general public and to the world at large of the enormous reserves which lie ready for action behind our iron walls—our first line of defence—and also behind the comparatively small permanently armed force which is commonly accepted as the English army, and which guards 277 million British subjects in an Empire covering nearly nine million square miles. The pageant is divided into six divisions comprising representatives of the home army, Indian army, Canadian army, Cape army, Australian army, and Colonial forces. In addition to the various feats of skill, tent-pegging, lemon-cutting, heads and posts, &c., there is a musical ride by the Royal Scots Greys (who will give place to the 2nd Life Guards next week) and a musical drive by the Royal Horse Artillery. From a practical point of view nothing is worthy of greater praise than the display by non-commissioned officers from the gymnasium at Aldershot, of which Colonel Fox is Inspector. Wrestling on horseback, the melée, sword *v.* sword, sword *v.* bayonet, sword *v.* lance, &c., mounted and on foot or mounted *v.* foot, are received with the same applause that has always characterised these exhibitions. The display by the Queen's Own Hussars strikingly brings out the difference between civilised and uncivilised warfare in regard to the wounded. The closing item of the programme represents the storming of an Afghan fort and involves a display of all arms. The Royal Military Tournament will remain open till Thursday next, June 11th, but intending visitors will do well to book their seats at once, as many applicants for seats are now turned away daily. With regard to the medical and sanitary arrangements they are as perfect as circumstances will permit, and the comfort and welfare of the general public are well looked after. Next week we hope to refer to the medical aspects of the tournament in fuller detail.

MOVEMENTS OF THE ARMY MEDICAL STAFF.

SURGEON-LIEUTENANT-COLONEL A. ADAMS of the Madras Medical Service, Residency Surgeon at the Court of H.H. The Maharajah of Jodhpore, has reported himself at Netley to join the Class of Bacteriology in the Army Medical School.

VOLUNTEER CORPS.

Artillery: 1st Kent (Eastern Division, Royal Artillery): Surgeon-Major R. R. Brown to be Surgeon-Lieutenant-Colonel. *Rifle:* 5th (the Hay Tor) Volunteer Battalion the Devonshire Regiment: Surgeon-Captain W. G. Scott, M.B., to be Surgeon-Major. 3rd (Sunderland) Volunteer Battalion the Durham Light Infantry; Surgeon-Captain R. J. Burns resigns his commission. 3rd (The Blythswood) Volunteer Battalion the Highland Light Infantry: Surgeon-

Digitized by Google

Lieutenant J. S. McConville, M.D., to be Surgeon-Captain. 3rd (the Buchan) Volunteer Battalion the Gordon Highlanders: The undermentioned officers resign their commissions:—Surgeon-Captain A. Blackhall, M.D., and Surgeon-Lieutenant P. B. H. Macleod, M.B.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Stuart Oliver, gent., to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADES.

Aberdeen Brigade: Surgeon-Lieutenant-Colonel W. Paterson, 4th Volunteer Battalion the Gordon Highlanders, to be Brigade-Surgeon-Lieutenant-Colonel. Plymouth Brigade: Surgeon-Major J. R. Thomas, M.D., 4th Volunteer Battalion the Devonshire Regiment, to be Brigade-Surgeon-Lieutenant-Colonel.

THE SOUDAN EXPEDITION.

There has been little to chronicle regarding this expedition during the past week. It seems, however, that there are signs of a forward movement taking place shortly. We do not think that much, if any, weight should be attached to various rumours and reports about the movements or intentions of Osman Digna or of the Dervish forces, for there is really very little reliable information on the subject. In spite of the great heat the health of the Anglo-Egyptian troops continues to be excellent, and the fact is a very creditable one to the medical and other services concerned, for it speaks well for the hygienic, hospital and transport arrangements of the expedition. But it is well to remember that the severe strain and test will come later when really active operations have begun. The latest Anglo-Indian papers are full of news connected with the dispatch of the Indian brigade for Suakin, which, as we know, has since arrived at that station. Brigade-Surgeon-Lieutenant-Colonel Calthorp is the principal medical officer of the brigade, which has been accompanied by the 31st and 32nd Native Field Hospitals. It is possible that the hospital accommodation on shore will be supplemented by one of the transport ships acting as a floating hospital, but we believe the troops composing the Indian contingent prefer to be treated on land.

THE DISPOSAL OF REFUSE AND NIGHT SOIL IN INDIA.

As everybody knows the dry earth system and the use of different forms of trenches for the disposal of night soil by burial are commonly adopted in India. It has often been suggested that this was open to the objection that the buried animal refuse might not be thoroughly disinfected and purified by the action of the soil and sun before the desiccated matters became blown about by the wind, especially in the case of shallow trenches in a highly porous soil. We learn from the *Pioneer Mail* that of late years the Indian Government has been carrying out experiments for the incineration of night soil and its reduction to ashes. This would no doubt be an excellent plan, especially for hill stations in India, and three kinds of incinerators have been used. Our contemporary speaks of the pattern known as the Henry Campion Incinerator as, on the whole, the simplest, cheapest, and most satisfactory.

ROYAL VICTORIA HOSPITAL, NETLEY, VOLUNTEER MEDICAL STAFF CORPS.

The Manchester Companies of the Volunteer Medical Staff Corps arrived at Netley on Saturday, May 23rd, for their annual training. The strength consisted of ninety-four non-commissioned officers and men under the command of Surgeon-Captain J. R. Renshaw. The other officers of the Companies present were Surgeon-Captain J. J. K. Fairclough, M.D., and Surgeon-Lieutenant A. Phillips, who were attached for duty respectively to the Medical and Surgical Divisions of the Royal Victoria Hospital. The Companies paraded daily at 6 15 A.M. to join the Medical Staff Corps parade and again at 8 40 for Hospital duties. The drills, &c., were arranged by the officer commanding and took place daily. The Companies paraded in drill order on May 29th, and were inspected by Surgeon-Lieutenant-Colonel B. M. Blennerhassett, A.M.S. The Companies left Netley on May 30th.

Examinations for twenty-five commissions in the Army Medical Staff and for twelve appointments in the Indian Medical Service will be held in London on Aug. 7th next and the following days.

John Alexander McMunn, M.D., Physician and Surgeon to the Royal Hospital, Chelsea, from Surgeon on Half-pay List, retires on retired pay.

Surgeon-Major James Magill, M.D., of the Coldstream Guards, is promoted to Surgeon-Lieutenant-Colonel.

Correspondence.

"Audi alteram partem."

"THE REGISTRATION OF MIDWIVES."

To the Editors of THE LANCET.

SIRS,—Dr. Fraser in his otherwise excellent letter published in THE LANCET of May 30th has fallen into one or two errors which require correction. He attributes the responsibility for the Midwives Registration Bill to the Midwives Institute. Now, Sirs, the Midwives Institute is not responsible for the measure in question. The Bill was promoted by the Midwives Bill Committee, a representative body principally composed of medical men and medical women. On this committee are two representatives of the Midwives Institute. These ladies have carefully avoided any interference apart from looking after the rights which midwives already possess. It is only fair to the Midwives Institute to make this statement, as it is receiving, and has received, a good deal of unmerited abuse. The promoters of the Bill have no objection to the Local Government Board as the supervising body under the State, but this Board is understood to be already overburdened with work. Its record, too, in respect to workhouse infirmary nursing seems to show that there is insufficient elasticity in it to make it a very suitable body for the governance of what Dr. Fraser calls "midwifery nurses." The principal difficulty, however, is that the Privy Council has imported itself into the matter on the initiative, not of the promoters of the Bill, as Dr. Fraser suggests, but of the Select Committee of the House of Commons on the Registration of Midwives. I do not propose to criticise in detail the points raised in the letter, most, if not all, of which have been at one time or another fully discussed by the promoters of the Midwives Registration Bill. I am only concerned at present to set Dr. Fraser right on certain questions of fact.

I am, Sirs, yours faithfully,

ROWLAND HUMPHREYS.

Midwives Bill Committee, Office, 12, Buckingham-street, Strand, W.C., June 2nd, 1896.

IN PRAISE OF CYCLING.

To the Editors of THE LANCET.

SIRS,—As cycling in health and disease is being written about in medical journals perhaps THE LANCET would allow me to say that I have found the moderate use of the bicycle to produce the most admirable effects on young people, especially girls who spend the greater part of the day shut up in houses of business and breathing in many cases a more or less vitiated atmosphere. "Spins" into the country when the labours of the day are over put strength, vigour, and vivacity into these young women, and the evening sun soon tinges their cheeks with the russet and ruddy hues of health. No doubt many people suffering from organic disease are benefited by judicious bicycle riding. I have a diabetic patient who lives in the country and visits me from time to time. In January of this year the specific gravity of his urine was 40 and he was looking and feeling very ill. A few days ago this patient called upon me and I was agreeably struck with his amended and robust appearance, and I was about congratulating myself on the effects the last mixture I had prescribed for him had produced when he informed me that the specific gravity of his urine was now 22, and that he had for some time left off taking medicine, had nearly eschewed the restricted diet, and had taken to the bicycle with energy. As to bicycles in present use, the chief complaint I hear about them is of their behaviour when ridden over a rough or cobbled roads. Then their bumpings and jarrings produce on their riders sensations of a painful and most disagreeable character. If this state of things could be remedied a boon of comfort would be conferred on

Digitized by Google

the bicycle-riding public. I had the pleasure of a conversation with four working men whom I met the other evening on a country road. Each had a bicycle of a bad description, and I was not surprised to hear from them that their mounts were rough in the riding and galled them awfully. Still, the machines were very useful to them, for they enabled the men to come into Lincoln to their work from a village six miles away in forty minutes which used to take them an hour and a half to walk. I am, Sirs, yours faithfully,

WILLIAM O'NEIL, M.D., M.R.C.P. Lond., &c.

Lincoln, June 2nd, 1896.

"RATIONAL THERAPEUTICS AND COMMON REMEDIES."

To the Editors of THE LANCET.

SIRS,—In the interesting and instructive paper published in THE LANCET of May 30th, under the above title, Dr. Samuel West asks for instances in which iodide of potassium has caused stoppage of the secretion of milk, and he also speaks of this drug as an efficient galactogogue. I must confess that I have always considered it to be quite the reverse; and in cases where I have thought it advisable to recommend a nursing mother to wean her infant I have been in the habit of prescribing from fifteen to twenty grains of iodide of potassium, to be repeated two or three times at short intervals, for the very purpose of stopping the flow of milk, and with very satisfactory and speedy results. In this treatment I am only following that recommended in the text-books of Playfair and Galabin.

I am, Sirs, yours faithfully,

R. BRUCE FERGUSON, M.A., M.D. Cantab., &c.

June 1st, 1896.

"THE CHURCH ANTI-VIVISECTION LEAGUE AND HOSPITAL SUNDAY."

To the Editors of THE LANCET.

SIRS,—We have reason to be very grateful to you for the increased publicity you have given to the circular of our committee by inserting it in your widely read journal. That you should, however, think it needful to ask for proof of the alienation of people from the Church by the attitude of, at any rate, a portion of the clergy on the vivisection question is a curious proof of what different circles we Londoners can dwell in. Of the feeling of which you seem altogether ignorant daily proofs are thrust upon me. I have, of course, no right in a public journal to mention without their consent the names of others in a matter concerning their spiritual life, but I can at least speak for myself. I am by this cause prevented from attending my parish church, where I should otherwise have been a regular worshipper, and have to go elsewhere to a church where I know the clergy to be anti-vivisectionists. Nothing (unless it be the attitude of many clergy at the time of the Eastern war) has ever been so great a strain on my faith as their indifference to this terrible sin, and I always carefully avoid as far as possible coming into contact with vivisectionist clergy, whether by contributing to their funds or otherwise, and I know I am but a fair sample of thousands in this. It is true that these clergy are generally unaware of the motives of our actions because respect for their sacred office seals our lips, but the fact remains all the same. Hardly a day passes without my coming across persons, both Anglican and Roman, who tell me how their faith has been strained, and, alas! too often weakened or destroyed. With your permission I will give a few typical instances out of the well-nigh countless examples which might be adduced. 1. A lady, very devoted to the services of a well-known Paddington church, told me recently she wanted to take a house in that neighbourhood in order to attend the church, but could not do so till she ascertained the views of the clergy about vivisection. 2. A regular and devout attendant at a well-known Kilburn church told me she had been obliged to leave and go to a church where the type of services was repugnant to her because the vicar of the former was not an anti-vivisectionist. 3. A lady in this immediate neighbourhood brought me in the winter an appeal she had received from the vicar of a North Kensington parish, saying she could not contribute unless he were an anti-vivisectionist. Unfortunately, I could give her no information on this point, but a little later he preached against vivisection and she then at once sent him a cheque. 4. Another North Kensington lady told me she had, alas! altogether given up attending church through having come across vivisectionist clergy. 5. A gentleman who writes the mystic letters M.D. after his name told me he hailed the existence of our society because he thought it would strengthen the faith of many waverers, and he mentioned that another anti-vivisectionist physician of his acquaintance had become almost an Unitarian on account of what he imagined to be the tone of the Church on this question. With regard to the theological argument in your article, I must confess I altogether fail to see how the extracts from St. Thomas Aquinas and St. Augustine support vivisection. It is an insult to common sense to assume that the right to kill and the right to torture are the same thing. A member of our league, already known to the public as an author, is preparing a catena which, when published, will conclusively show the real tone of Christian theology on this point.

I am, Sirs, yours obediently,

A. L. WOODWARD,

Hon. Sec., Church Anti-vivisection League.

Lancaster-road, W., May 29th, 1896.

*** We publish this letter with great pleasure: first, on account of the motto at the head of our correspondence column; and, secondly, because it is interesting to see the ideas that some people have as to what constitutes "proof." It is a little hard upon Ladies 1 and 2 to assume their alienation from the Church. The Church is not a building. As to Nos. 3 and 4 we would direct the writer's attention to the twenty-sixth of the Articles of Religion.—ED. L.

"THE USE OF GUAIACUM IN THE TREATMENT OF CHRONIC GOUTY AFFECTIONS."

To the Editors of THE LANCET.

SIRS,—In the report of my observations at the Royal Medical and Chirurgical Society on Sir Alfred Garrod's paper on the Use of Guaiacum in the Treatment of Gout reference is made to a local method of treating the acute manifestation of this affection which I have employed with success. With your permission I will give the formula in full. I take half an ounce of iodide of potassium, dissolve it in half a pint of rectified spirit—methylated spirit is used in hospital practice—add one ounce of soap liniment, and then half a drachm each of oil of cajeput and oil of cloves. A piece of lint is soaked in this mixture, wrapped round the affected part, covered with protective and kept in place by a bandage. It acts as a powerful counter-irritant, and the inflammation usually subsides in from twelve to twenty-four hours. In addition I not uncommonly give a drachm of colchicum wine with ten grains of iodide of potassium three times a day. These large doses of colchicum wine induce brisk purgation, sometimes accompanied by vomiting, but they speedily cut short the attack. This mode of treatment is especially useful in the case of robust, full-bodied men in active employment, to whom the loss of a day's work is a serious consideration. In sciatica, lumbago, and rheumatism affecting one joint the local application of a liniment containing half an ounce of salicylate of sodium, half a drachm of oil of cajeput, fifteen minims of oil of eucalyptus, and half an ounce of soap liniment in six ounces of rectified spirit affords prompt relief.

I am, Sirs, your obedient servant,

Welbeck-street, W., May 31st, 1896. WILLIAM MURRELL.

"NERVE GRAFTING FOR INJURY."

To the Editors of THE LANCET.

SIRS,—My attention has just been drawn to your notice in THE LANCET of March 7th, 1896, of the case of nerve grafting for injury which I reported in the *Medical News*. As I believe I stated in that report, the man was discharged the service of the army because of this disability. After the report was published and about five months after operation I received a letter from him asking aid in securing a pension. In this communication he stated that there had been no improvement resulting from the operation. Interested as he was in obtaining a pension it is barely possible that had there been any improvement he would have concealed it, but from what I know of the man I believe he is honest in his statement. The time which had

Digitized by Google

elapsed (five months) has proved in some similar cases too short a period for return of function. Technically the operation was successful, and I still have some hope that eventually function may be restored. I can see no reason why if success should ever result in similar procedures it should not have been achieved in this case. I am prompted to make this communication in view of your closing remark in the notice in your issue referred to: "It would have been very interesting to know whether any improvement resulted from the procedure."

I am, Sirs, yours faithfully,

A. E. BRADLEY,
Captain, Medical Department, United States Army.

Fort Yellowstone, Mammoth Hot Springs, Yellowstone National Park, Wyoming, May 18th, 1896.

THE DUNBAR WATER-SUPPLY.

To the Editors of THE LANCET.

SIRS,—So many letters have reached me from various quarters inquiring about rumours regarding Dunbar water-supply and an alleged fresh outbreak of typhoid fever that I shall be much obliged if you will make public the following facts. All such rumours are absolutely false. The old water-supply is entirely cut off, so that it is impossible for any of it to be used. The new water-supply is perfectly satisfactory and the water has been certified to be of the most excellent quality. There has been no case of typhoid fever notified since Feb. 4th last, and, indeed, Dunbar as a rule is conspicuous by its freedom from infectious disease of any description. Intending visitors, therefore, can come to enjoy Dunbar with full confidence in its safety as one of the healthiest seaside resorts in the country.

I am, Sirs, yours faithfully,

G. T. SINCLAIR, M.D. Edin.,
Dunbar, June 1st, 1896. Acting Medical Officer of Health.

THE ARMY MEDICAL STAFF.

To the Editors of THE LANCET.

SIRS,—Will you permit me to urge on the "second-rate and inferior" members of the profession to seize this favourable opportunity to enter the Army Medical Staff? Within a few years they will equal in professional knowledge the *superior* men and far surpass them in the knowledge of the world. In the army there are disadvantages, but they are few and insignificant as compared with the marked and numerous advantages of service in the Army Medical Staff. The pay is good, better than the remuneration in private practice; the work is less arduous and more pleasant, the worry and anxiety are less, the taskmasters are fewer, holidays are more certain and more frequent, friends are more easily made, jealousy is almost unknown, the advantages of travelling at Government expense are not to be despised, and the opportunity of retiring and living a life of ease at a comparatively early age is not to be overlooked. I do not deny that the Army Medical Staff have grievances which the War Office authorities would do well to remove, but I do assert that, compared with the drawbacks and disadvantages of life in private practice, they are almost microscopic. As "Brigade-Surgeon, A.M.S.," and "Active List" have not signed their letters I conceal my identity under the disguise of

June 2nd, 1896. SURGEON-CAPTAIN, A.M.S. (Retired).

"A DECEPTIVE ETHER INHALER."

To the Editors of THE LANCET.

SIRS,—As the original makers of Clover's ether inhaler we wish to deny the parentage of the inhaler mentioned by Mr. Paul. Many imagine that all Clover's inhalers are now manufactured by us, so that this disclaimer is necessary. We may mention that this is by no means the first case of "transposed viscera" that has come to our personal knowledge, and we cannot help thinking that, at any rate in this case, professional etiquette, which prevented our patenting this apparatus, has often brought a good and useful instrument into ill repute.

We are, Sirs, yours faithfully,

MAYER AND MELTZER.

Great Portland-street, W., May 30th, 1896.

LEGISLATIVE PROHIBITION OF THE SALE OF ALCOHOLIC LIQUOR.

To the Editors of THE LANCET.

SIRS,—I have read with interest and profit the leading article in THE LANCET of May 30th on the above subject. Medical men see more of the terrible national disease, alcoholism, and are better able to judge of its causes and consequences than any one else. We ought, therefore, to be in a better position than other people to suggest the best methods for dealing with it. Indeed, intelligent legislators will naturally expect us to furnish them with information which shall guide them in framing laws dealing with the subject. Your article enables us to see what methods have been tried elsewhere, how far they have succeeded, and in what respects they have failed. It is evident that drastic laws, like drastic medicines, are likely to do more harm than good, since they generally lead to defiance and contempt of law. Hence, as you observe, "the policy of prohibition has been on the whole a decided failure," and that, on the other hand, "great success has attended prudent measures of regulation and repression." The zealous advocates of prohibition commit two errors. They underrate the importance of education and they overrate the power of law. Until far greater care is taken in the training of youth, until a far more intelligent system of education is adopted, one which shall develop in a balanced manner the physical, mental, moral, æsthetic, and religious faculties, widening, elevating, and beautifying the sphere of daily life, men will grovel within narrow limits and will seek for enjoyment in mere animal gratification. Now since alcohol engenders a sense of contentment and pleasure more readily than anything else which he can command the uneducated man flies eagerly to that, and if he has the means of purchasing the much-desired agent he will indulge therein. The craving for alcohol amongst the masses of the people is lamentably common. Restrictions will be tolerated, but the attempt to suppress the sale of the favourable beverages would excite fierce resentment. The cure for national intemperance must therefore be a gradual process depending on the more thorough education of youth on the one hand and gradually increased restrictive laws on the other.

I am, Sirs, yours faithfully,

Manchester, June 3rd, 1896. P. M.

THE CHILDREN OF THE STATE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 23rd you referred to a severe criticism upon the report of the Poor-law Schools Committee, and showed that those whose care of pauper children in the past had been so seriously called in question by the report were not content to sit down quietly under the stigma laid upon them by the conclusions of the committee. The feeling of hostility towards the tenor of the report is undoubtedly growing. I should like to direct attention to a report made to the Shoreditch board of guardians by their committee charged with the visitation of the cottage homes belonging to the parish of St. Leonard, Shoreditch, in which the contentions of the Schools Committee are referred to in very severe terms. The several points of which much is made in the Schools Committee's report are specially mentioned, and the construction placed on the evidence seriously called in question. Without going over the ground covered by the local committee I may say that their view is that the report of the Schools Committee is, in brief, a statement of conclusions arrived at prior to the taking of evidence, and is a founding of general impressions from isolated examples rather than a judgment based on comprehensive views of debatable matters. Too much, say the local committee, is made of the particular in the way of formulating therefrom recommendations to govern the whole. "Bias" is the term which the critics would apply to the report, and this in a direction hostile to the past action of the guardians and their officers. The improvement of the system hitherto in vogue with the advance of ideas is never acknowledged, and the too sweeping condemnation of the school system by reason of a few statements showing up its bad features in particular instances is held to be the fixed purpose of the departmental committee. One strong point put forward

Digitized by Google

by the local committee at Shoreditch is that the educational system as now practised has been shown by no less an authority than Mr. Lockwood, one of the inspectors of the Local Government Board, to have resulted in the absorption in the army of the respectable wage-earning classes of the country of almost the whole of the thousands upon thousands of pauper children who have in the past been under the care of guardians. The system of dealing with children in Shoreditch is shown to have anticipated many of the suggestions of the departmental committee and to be working well. The report is looked upon as reproducing too faithfully the views of its members as known prior to the appointment of its writers, while the manner of treating the evidence of witnesses, according as it did or did not fit in with these preconceived ideas, is referred to as a species of biased favouritism. The opinion, from a perusal of this criticism and of others, is that the idea prevails that the report and its recommendations go altogether beyond the ground covered by the evidence. In these circumstances it is pleasing for boards of guardians to be assured by none other than the Duke of Devonshire, as Lord President of the Council, that no action will be taken with a view of adopting the recommendations of the committee before plenty of opportunity has been given for the voicing of the feelings of those at present charged with the administration of the laws touching pauper children and the manner of the upbringing and education of these children. If the departmental committee have in any wise overstepped the bounds of general fact and dealt with points only from the view point of individualism their case will be weakened wherein they seek to show the absolute necessity for reform in the direction of taking pauper children out of their present sphere and of placing them in London under one central authority.—I am, Sirs, yours truly,

OLIVER TWIST.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Dr. Niven on Sanitation among the Manchester Jews.

THE twelfth annual meeting of the Manchester Jewish Ladies' Visiting Association was held on the 21st ult. in the town hall. The report stated that the work of the association was energetically carried on; that 225 houses on an average were visited every week; that besides offering such suggestions as might promote cleanliness in the homes of the poor the district visitors distributed carbolic powder and had sold 20 cwt. of carbolic soap, besides supplying materials in order to enable the poor to carry out the requirements of the Health Department of the corporation as to cleansing their houses. The financial statement was satisfactory. In moving the adoption of the report Dr. Niven said "the condition of health of the Jewish community in Manchester offered a very interesting and pleasant spectacle." Year after year the death-rates in the Jewish quarters offered a striking contrast to those of neighbouring districts. The death-rate for the first quarter of this year was 17·3 in Red Bank and 18·5 in Strangeways. They are inhabited chiefly by poor Jews and contrast strongly with the adjoining district of Angel Meadow with a death-rate of 50·9, and with St. George's Central and Ancoats West districts with rates of 39·2 and 42·0 respectively. It was no exaggeration to say that the Jewish community presented a death-rate less than half that of some of the neighbouring districts. While it is difficult to understand all the factors helping to produce the contrast, probably the most important are the prevailing temperance and, perhaps even more, the great care which the Jewish people take of their children. Dr. Niven, so far as his inquiries went, thought they were probably better clothed, fed, and cared for than the children in many other parts of Manchester. He believed that the Jews in their polity looked to the mothers staying at home to take charge of the children while the men went to work. As is well known, it is the custom for a very large proportion of the non-Jewish mothers to go out to work, leaving their children in the care of others. "It was interesting to find that the death-rate as regarded children was low among the Jewish community where the mothers stayed at home and looked after their children, and so high in neighbouring districts, where so many mothers went to work, leaving their children to the care of others." He could not think economically that the Lancashire custom for the mothers to go out to work was a good one, and the contrast as to death-rate was interesting because it was in spite of what we rightly lay stress on—i.e., the want of cleanliness among the poor Jews. "He did not think any of the Jewish people would claim—and especially those who had recently come from abroad—that they were more cleanly and nice in their habits than others. ..... They were in many respects extremely slovenly and dirty in their habits, and effluvia which arose from decaying vegetables and from the extraordinary cooking operations which went on in the houses were in many respects often very disagreeable." He spoke also of the poor Jewish people being "more apt to accumulate dust than their neighbours," a pleasing and delicate euphemism, and dealt very tenderly with the frightful proclivity to dirt that seems ingrained in most of the poor Jews. The strange thing is that they flourish in spite of their habits and surroundings, which seems to point to great racial vitality. They no doubt owe much to their temperance as to alcoholic drinks, while as to food they are not frugal, but rather lavish, and though their cooking is peculiar and not always as cleanly as we should like their rich, greasy messes seem to suit them.

Milk Adulteration.

Some cases involving points of interest under the Food and Drugs Act were heard at the city police-court on the 21st ult. An inspector took a sample of the milk sold by a small shopkeeper and it was found to have been deprived of fat to the extent of 27 per cent. The shopkeeper declared he sold it exactly as he received it from a wholesale milk dealer. A sample of milk sold by the latter had been deprived of 26 per cent. of fat. The wholesale dealer in turn declared he sold it as he received it from the farmer. Samples, therefore, were taken on different occasions of the farmer's milk as it was delivered at the station, which, according to the analyses of Mr. C. Estcourt, the city analyst, "had been deprived of fat to the extent of from 16 to 45 per cent." The analysis of Mr. Charles Blades, a member of the Society of Public Analysts, produced very different results, and it was agreed that the summonses should be adjourned for a fortnight to allow of these gentlemen making a joint analysis. It should be said that two inspectors went to the farmer and asked for a sample of the milk as it came from the cows, but he would not allow them to have it until it had passed through the refrigerator. In the second case the retail dealer and the wholesale dealer declared they had sold the milk, which had been deprived of much of its fat, as it had been delivered to them, and a sample taken of the milk as it was supplied by the farmer showed that 32 per cent. of the fat had been removed. The defending solicitor contended that the milk-dealers had combined to throw all the blame on the farmers and complained that the inspectors attached to the sanitary department of the town hall took advantage of "the poor unsophisticated Cheshire farmers"; notwithstanding which touching appeal the farmer was fined £5 and costs and the summonses against the dealers were withdrawn. Three other milk retailers were fined for adding water.

Summer Camp for City Boys.

Ever since 1883 a camp for poor city boys has been formed each summer as part of the work of the Boys' Refuge, a most valuable Manchester charity. The first year it was at Morecambe, and since then at Llandudno, Ansdell near St. Anne's, and for the last three years at Birkdale, Southport, where the camping-ground has been placed at the disposal of the committee by Mr. Wild-Blundell, the lord of the manor. It is on sandy soil, is near the railway-station, and only a few minutes from the sea. The camp is formed at Whitsuntide and continued to the end of the summer, during which time batches of poor boys, about 120 at a time, are kept under canvas for seven days, being replaced every Monday by a fresh contingent. Last year 1461 boys had a week's holiday, and it is hoped that this year 1500 may be received. The movement is helped by many philanthropic people. A large corrugated iron structure, known as Byrom Hall, has been given by a lady and gentleman of that name from Bury, which is of great use in bad weather, and many of the tents have been supplied by friends. "In this and other ways—by gifts offered, camp equipment, &c.—the cost of maintenance is sensibly reduced, and with the sums contributed annually by the lads the committee are enabled to provide for them a very enjoyable and health-giving summer holiday at a cost of 6s. each per week." A sergeant and his wife, with the help of one or two junior

Digitized by Google

officers, look after the boys, and members of the committee go down from time to time. The city missionaries, district, visitors, and others interested in the poor find plenty of deserving cases, and the candidates are always in excess of the accommodation. While under canvas a sort of uniform is worn, which identifies the boys as belonging to the camp, and allows of the fumigation and storing of the temporarily discarded clothing. Before leaving Manchester the boys are medically examined by Dr. Ledward, and while they are under canvas by Mr. Reinhardt Anderson of Southport, the honorary medical officers. Ten or twelve are allotted to each tent. The bugle-call for rising is at 6.30, then come a brief drill, prayers, and breakfast at eight. Tents are then swept out and cleansed, after which, if the tide serves, the boys parade for bathing. Dinner is at 12.30, tea at 5, supper at 9, and after prayers, which cannot be of excessive length, the lads go to their tents at 9.30. The time passes with a little drill, various games, and rambles along the shore, a blissful change from the stifling slums and alleys of Manchester on a hot summer's day. The food is good and substantial and there is no stint. At the recent opening for the season by the Mayor of Southport many friends were present, who could not fail to be touched by the appearance of these lads from the slums. Some few seemed robust, but the great majority showed in their pale faces and stunted growth the degeneration of race, in the production of which the unhealthy conditions of life in the low districts of our large towns are important factors.

June 2nd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Proposed New Asylum for Pauper Lunatics.

As a result of a conference between representatives of the parish council and the Lunacy Board it has been agreed that the parish council will be under the necessity of providing a new asylum to accommodate pauper lunatics to the number of 400 or 500. The present asylum at Morningside is able to deal with only about one-third of the number of lunatic paupers, which are under the care of the parish council, hence the necessity for additional accommodation. It is expected that the building connected with this scheme will necessitate an outlay of at least £50,000. The question of a site for the new asylum has still to be considered.

Health of Edinburgh.

At a meeting of the Public Health Committee it was reported that the number of deaths during the month of May was 353, giving a death-rate of 15·31 per 1000. The average death-rate for the preceding five years was 17·31 per 1000. Zymotic diseases had proved fatal in 6·51 per cent. of the total mortality.

June 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Irish Medical Association.

AT the meeting of this association, which was held in Dublin on June 1st, a strong opinion in favour of the extension of the English Superannuation Measure to Ireland was expressed by many of the speakers. Mr. Horace Plunkett, M.P., with Dr. Jacob, the secretary of the association, have been very active in the matter, and there seems to be some hope that a Bill embodying an arrangement by which a superannuation allowance would be secured to retiring Union medical officers may be passed this Session.

The Royal College of Surgeons in Ireland.

The annual meeting for the election of the President and Council of the College took place on June 1st, when Mr. William Thomson and Mr. Kendal Franks were elected President and Vice-president respectively for the ensuing year. The only changes which have taken place in the *personnel* of the Council are indicated by the disappearance of the names of Mr. William Stoker, who resigned his seat in May in order to become an examiner, and of Mr. Cranny, who was elected on that occasion to fill his place. Sir W. Thornley Stoker, the outgoing President, and Sir William Stokes, recently one of the examiners in surgery to the College, occupy the two vacancies. The new Council will be obliged to deal with a very unpleasant matter in the shape of a movement which has taken place in the medical school of the College in reference to the recent election of Dr. E. Winifred Dickson to the position of examiner in midwifery and gynæcology. The students have held a meeting, and in addition to a request for Miss Dickson's resignation have threatened that unless their demand is complied with they will leave the school and College to obtain their qualifications elsewhere. Dr. Dickson, who is gynæcologist to the Richmond Hospital, is, of course, highly qualified for the post of examiner. The wisdom, however, of the College in appointing any young lady to examine young medical students in midwifery and obstetrics is considered by many to be open to question.

Death of Mr. Robert Gilmer, L.R.C.P. & S. Edin.

I regret to announce the death, on May 24th, at his residence, Ballymena, of Mr. Robert Gilmer, in his fifty-first year. He has been ailing for several months, so that death was not unexpected. Mr. Gilmer studied in Belfast and after becoming qualified began practice in Ballymena, where for the past twenty years he has enjoyed the respect and confidence of a large *clientèle*. The greatest sympathy is felt for his wife and family in their very sad bereavement.

The Condition of the Belfast Workhouse.

Mr. Agnew, Local Government Board inspector, in his report on the condition of the workhouse in Belfast, states that the accommodation for the infirm classes, both male and female, is inadequate and inefficient, particularly for the infirm women, a number of whom were located in sheds used as living and sleeping rooms. In the school building the day-room accommodation for the male attendants is inadequate, while the women had no day-room at all. The inspector recommends that structural changes should be made to meet the wants of these classes. In the healthy nursery, where 50 mothers and 59 children were located, there was no bath or lavatory accommodation. There was also no lavatory accommodation for a large number of healthy men and women. The inspector suggested that structural changes were necessary in the infirmary so as to provide separate wards for phthisical and erysipelas patients. The water-supply in the infirmary was inadequate. The school-yard was in a discreditable condition. At the meeting of the board of guardians, held on May 26th, a committee was appointed to consider this report of the inspector.

Queen's College, Belfast.

Dr. Whitaker, medical officer of health for the city of Belfast, has been appointed lecturer on Sanitary Science at Queen's College, Belfast.

Presentation to Mr. John Wilson.

Mr. John Wilson, recently appointed medical officer of Enniskillen Union, after having been for a period of sixteen years dispensary medical officer of the Barronstown district, co. Louth, was last week presented at a meeting in the Dundalk Club with an address and purse of sovereigns. The presentation was made by members of the medical profession, the hunting men of the district, his former patients, and by the general public.

The Queen's College Union, Belfast.

At a meeting of the General Committee of the Students' Union, held at Queen's College on May 29th, it was reported that the new union buildings were progressing rapidly, and that financially, after paying for the erection and furnishing of the union, there would be about £1000 over for investment. The draft constitution was considered and adopted, and the bursar of Queen's College was appointed auditor. It is expected that the new union will be ready next session, and as early in the coming year the jubilee of the College is to be celebrated this would be a very suitable occasion for the public inauguration of an institution which will serve as a bond of union between students, graduates, and officials of the College.

Hospital Saturday in Belfast.

The annual street collection on behalf of the Royal Hospital was taken up in Belfast on May 30th, and, despite the beautiful weather and the large number of collectors, who threw themselves most energetically into their work, the

Digitized by Google

amount collected was less than last year by about £50, so that when necessary expenses are deducted there will only be a sum of £230. The movement, judging by results, is not increasing in popularity; and amongst many the feeling is growing that the hospital must be put on the city rates as, unlike the similar charities in Dublin, it is not subsidised by the Government contributions. One reason why less interest is being taken in the Royal Hospital is undoubtedly the large number of smaller charities of every kind which have in recent years sprung up all over Belfast and which take many of the old hospital subscribers.

The Health of Belfast.

The report presented to the City Corporation on June 1st by the medical officer of health shows that the condition of Belfast from a health point of view is most unsatisfactory. For the five weeks ending May 23rd the death-rate was from all causes 26·9 per 1000, while in Dublin it was 24·8, and in Cork 18·9; in Belfast the death-rate from zymotic diseases was 3·6, while in Dublin it was 1·6 and in Cork 0·1; in Belfast from chest affections it was 9·6, in Dublin 7·6, and in Cork 7·0. Various theories are put forward to account for the continued extraordinary high death-rate in Belfast; it is said, for instance, that the death-rate is calculated on a population of 277,354, which is much too low, as the probable present population is close upon 300,000; again, it is said to be due to the large pauper population, to the nature of the soil, or to the character of the manufactures, and to the absence of notification of disease; but in the discussion in the Corporation on the question it was pointed out by one of the members that the matter could not be dealt with by such generalities, and that it would be infinitely better if the members of the public health committee would go to the root of the matter and ascertain what was the real cause of the undoubtedly high death-rate of the city. Some progress has been made in reference to the long-talked-of erection of an infectious hospital, and the public health committee have selected two sites as suitable—one at Old Park-road and the other in the asylum grounds at Purdysburn. There is one slight morsel of comfort in that the birth-rate of Belfast is the largest of any district in Ireland. One thing is quite evident, the death-rate of Belfast is exceptionally high, the causes of which should be found out and removed. Birmingham affords a notable example of what can be done in this direction.

June 2nd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Craving for Salt.

IT may seem strange that this well-worn subject should at the close of the nineteenth century be discussed at the Société de Biologie (May 23rd). M. Lapicque, after reminding his audience that chloride of sodium is consumed as an article of necessity by nearly all races and that most of the lower animals are fond of it, tells us that there are, however, exceptions to this rule. The herbivora betray a greater liking for the salt than the carnivora, and in the same way agricultural populations, who are more or less vegetarians, are invariably large consumers of it. The tribes who eat no salt lead a pastoral or nomadic existence whose regimen is almost exclusively animal. This led Bunge to formulate the theory that as vegetables contain principally potassium salts these latter replace the sodium salts in the economy, and the vegetarian instinctively craves for common salt in order to compensate for its loss through the kidneys. This theory is, however, weak, for it does not explain why certain peoples who have not access to sea salt replace it by salts of potassium obtained by the incineration of plants. Such a people are the negro inhabitants (1,000,000) of the French Congo between Lake Sangha and Lake Tchad. Salt is unknown in this vast territory, which is as large as France; for it is substituted an artificial salt extracted from a certain number of selected plants, whose ashes are washed and their potassium salts crystallised out. Samples of the salt have been analysed and found to be composed of potassium salts only. When on their first entrance into the country the French endeavoured to sell common salt they found it unsaleable, the natives preferring their own. This disposes of the theory propounded by Bunge, and to my mind weakens another theory advanced by Ringer and others, claiming for potassium salts the property of a protoplasmic poison and cardiac depressant. M. Lapicque inclines to the belief that salt is only of use in procuring for man and animals a gustatory stimulus. M. Trouessart reminds us that dearth of salt in besieged cities has been made up by the use of saltpetre. M. Giard told his colleagues the story of the chimpanzee of the London Zoological Gardens which, deprived of salt, took to drinking its own urine. As soon as it was provided with a block of bay salt it ceased to drink its urine and used to sleep with the salt held tightly in its arms. According to M. Samson oxen and sheep will on large farms abstain for weeks together from the salt placed within their reach, whereas at certain other periods they eat largely of it. This variability of appetite for salt is due to the variation, according to the season of the year, of their diet.

A New Method of Treatment by Heat of Soft Chancres.

Dr. Audry of the Toulouse Faculty has devised a modification of the heat treatment of soft chancres introduced three years ago by Dr. Welander of Stockholm. Dr. Audry employs radiant heat supplied by the thermo-cautery, the button of which is held for a few seconds at a distance of three or four millimetres from the sore previously washed and dried. Should the point of the thermo-cautery be fine it must be brought to a white heat; if larger, to a dull red heat. Exposure to this radiated heat for the period indicated has the effect of thoroughly drying the ulcer, on the edges of which there now appear sanguinolent striæ. Too long exposure determines a raising of the surrounding epidermis and a reddening of the skin. A single *séance* is stated to be usually sufficient to transform the chancre into a simple ulcer, which soon cicatrises under the influence of any antiseptic powder. The rapidity of the healing is due to the absence of the scab that always follows the direct application of actual or chemical heat. The pain is said to be quite endurable, being less than when the actual cautery is employed.

The late Dr. Stoltz.

The death on May 22nd, after a very short illness, of Joseph Alexis Stoltz deprives French obstetric medicine of one of its chief celebrities. Born in 1803 at Andlau in Alsace, his father being an *officier de santé*, he studied at Strasbourg, graduating M.D. at the age of twenty-three years. He at once selected obstetrics and gynæcology as his special studies. Appointed *professeur-agrégé* in 1829, he became five years later Professor of Obstetrics of the Strasbourg Faculty and Director of the Departmental Midwifery School. In 1846 he was appointed Dean of the Faculty. He was a *membre associé national* of the Paris Academy of Medicine. Commander of the Legion of Honour, and had filled the offices of member of the Municipal Council of Strasbourg and member of the Conseil Général of the Bas-Rhin. Opting for France after the catastrophe of 1870 he followed the Faculty of Strasbourg in its migration to Nancy, where he retained the same posts of Professor and Dean. There he remained until 1880, when he retired to his native place, Andlau, picturesquely situated at the foot of the Vosges. Here he became the Good Samaritan of the district, nor did he refuse an occasional consultation.

June 2nd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Official Report on the Langerhans Case.

THE death of a child after an injection of diphtheria antitoxin, which I reported lately in these columns, has induced the legal authorities to order a careful examination of the serum used in this case. The examination was performed by Professor Ehrlich, Director of the Royal Control Office, and the results are now published in the official papers and in the *Berliner Klinische Wochenschrift*. The report states that the serum before being admitted to sale had been tested (by control experiments) according to the existing regulations by the office. The serum, then registered under No. 216, showed 100 immunisation units per cubic centimetre, and absolute sterility and the normal quantity of carbolic acid. After the fatal accident the antitoxin No. 216 was again tested and proved to be quite unaltered. By careful inquiries in those hospitals where other bottles of the antitoxin No. 216

Digitized by Google

had been sent (Charité Hospital, Berlin; Julius Hospital, Würzburg; General Hospital, Hamburg; and municipal hospitals in Magdeburg and Krefeld), it was ascertained that in no instance had unfavourable symptoms been observed. In one of these hospitals a tenfold dose was administered to a boy one and a half years of age without any harm resulting; in another of them a series of children received injections for immunising purposes and remained quite healthy. The report concludes that from a clinical as well as from an experimental point of view the serum No. 216, used in the Langerhans case, must be regarded as a normal one. The death of the child is, therefore, not to be imputed to the antitoxin.

Hygiene in Printing Offices.

A Bill providing for hygienic improvements in printing offices has been proposed to the Federal Council by the Imperial Chancellor. It specifies that the rooms of the offices must be 4 metres (= 13 feet) in height, and must contain at least 15 cubic metres (= 530 cubic feet) of air for every man employed therein. The floor must be smooth, and the walls must be painted with oil paint renewed every five years. The type cases must be provided with pedestals to avoid the accumulation of dust beneath them. Stereotype work is to be done in special rooms efficiently ventilated. The type cases are to be cleaned in the open air and by the aid of bellows only. Ample lavatory accommodation is made compulsory by the Bill, which gives very precise directions in this matter. One washhand basin at least must be furnished for each five workmen, soap and towels are to be supplied to them free of charge, and a cloakroom separated from the workrooms is to be provided. This Bill, which is viewed very unfavourably by the employers, is on the other hand declared by competent medical men to be very useful. Dr. Lewin, a Lecturer on Toxicology at the Berlin University, points out that whilst the German insurance laws oblige employers' associations to indemnify workmen in case of accidents they are entirely unprotected against the chronic influence of poisons. As printers are liable to suffer from the effects of lead—one of the strongest poisons—he thinks that preventive measures are necessary, but the Bill ought, in his opinion, to be extended to other trades where lead is used, and he specially mentions some of the home industries where the workmen's children inhale dust impregnated with lead. The children of dial-plate painters, for instance, even if born healthy die in a few months with convulsions. In a village of Hesse, where pottery is glazed by home workers, 71 per cent. of the children were sickly, 50 per cent. died within the first five years, and the survivors suffered from hydrocephalus or macrocephaly.

Deaths of Medical Men.

Dr. Henle, one of the best German anatomists and Professor of Anatomy at the University of Tübingen, in Würtemberg, died in that town on May 23rd. He began his medical career abroad as an assistant to the great physiologist Donders of Utrecht, in Holland. He was then appointed professor at the Universities of Marburg, Rostock, Prague, and Tübingen respectively. The number of his anatomical publications is very great, his most renowned work being the "Handbook of Topographical Anatomy." His death will be lamented not only by the members of the profession but also by lovers of the fine arts, because he employed his anatomical knowledge in the interpretation of the problems which present themselves to artists. He published an essay on the Laocoon group, another on the works of Michael Angelo compared with those of the ancient masters, and a series of articles which were collected under the title of "Papers on the Plastic, Mimetic, and Dramatic Art."—Dr. Agathon Wernicke, chief medical officer to the Berlin police, died in Berlin on May 26th. He was one of the organisers of the University of Tokio, in Japan, having been summoned there together with another German medical man in 1874. He principally occupied himself with epidemiology and medical geography, and lectured on these subjects at the University of Berlin. He died from diabetic gangrene, and it caused much surprise that he allowed himself to be attended by a quack and declined to submit to an amputation which was recommended by an able surgeon.

The Apothecaries' Board.

A new board in connexion with the Government Medical Department is now instituted by a royal order. It has to deal with all matters concerning the pharmaceutical profession and is to be consulted if any alterations or reforms are intended. It may also advise the Government to alter the laws and regulations when circumstances require it. The board consists of the Director of the Medical Department as chairman, three medical members of this department, four qualified apothecaries (who must be owners of pharmacies), and four other qualified apothecaries employed in licensed pharmacies. The board is to meet at least once a year.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Infectious Disease in Schools.

AT Turin the other day Dr. Angelo Mosso, Professor of the Institutes of Medicine in the University, delivered before the Società Piemontese d'Igiene a lecture on the above topic. No man can be so "wholesomely practical" as the laboratory worker on due occasions, and Professor Mosso showed at once the grave importance of school hygiene by demonstrating that in the dust swept up from between the benches occupied so many hours each day by the scholars any quantity of pathogenic bacilli may be found—among them specimens of the bacillus diphtheriticus. In fact, it was at the instance of Professor Mosso's colleague, Professor Bizzozero, that the former physiologist prepared the lecture he has just delivered. "Every commune," so runs Article 110 of the legislative enactment for the observance of public hygiene, "must have its schools visited at least twice a month during scholastic hours, and without previous intimation by the communal sanitary officer or by medical practitioners specially told off for the purpose." This precaution, however, Professor Mosso proved by official documents to be quite irregularly enforced in even the best organised communes, like Turin itself, where there are over sixty schools, urban and suburban, to say nothing of private ones, and where the sanitary inspection prescribed by Government has to be carried out by only two medical men. Appealing to the precedent of Great Britain, particularly London, Professor Mosso insisted on the adoption in Italy of a similar thorough organisation if her large towns are to have so comparatively clean a bill of health as London, and especially London schools. Even where the "Commissione di Vigilanza," established by the Government quite recently for the protection of elementary schools, is fully organised, it is so far defective that the sanitary officer is without due authority and is without the means of effecting the reforms of which he sees the necessity. This is a grave omission, for, according to Professor Mosso, Italian municipalities "sono restii ai progressi dell 'igiene" (resist hygienic progress), and the want of power to coerce them explains the paralysis of the medical arm and the disastrous prevalence of infectious disease in young Italy. Meanwhile, urged the lecturer, in the present state of the kingdom (financially and politically incapacitated for the graver social reforms) the various Società d'Igiene throughout its borders must educate the public mind, show the dangers incurred by tender youth *in statu pupillari*, and prepare for such a methodical and medically inspired regulation of school hygiene as the Government may give effect to at the first favourable opportunity. Turning to sanitary details in scholastic life Professor Mosso proved that something more than ventilation (deficient as that usually is) requires attention. The *personale subalterno* (the subordinates charged with cleaning the school) must be taught hygienic principles and made to observe them. In the first place the benches should be only so long as to admit of their easy displacement for cleansing purposes under and below them. The old sweeping methods (with brooms), which simply stir up the dust and diffuse it in the air only to settle down again, must be abandoned. Three or four times a week (better every day) the floor should be laid with damp sawdust, afterwards diligently swept up, while twice a month the walls should be carefully washed. For such service the *personale subalterno* should be doubled or trebled. Again, the Società d'Igiene should initiate popular courses of hygienic instruction for schoolmasters and schoolmistresses, especially as to the origin, nature, and diffusion of infective disease, and should publish short, practical treatises addressed to the community so as to ensure intelligent coöperation between school managers and municipal authorities, between teacher and parent. Such a twofold propaganda can be fraught with

Digitized by Google

nothing but good for "the Italy that is to be." Professor Mosso's recommendations were unanimously adopted by the society, which at its next sitting will discuss the same physiologist's report on "Physical Education in Schools," a subject on which the writer of "The Pathology of Fatigue" expatiates with peculiar authority.

The Premier on the "Direzione di Sanità."

In his great speech on the administrative programme of the Government the Prime Minister, the Marchese di Rudinì, has just made an important statement as to the "Direzione di Sanità" (public health department). That department laboured under two constitutional defects which fructified in much irregularity and inefficiency. It had a "scuola d'igiene" (a training college of hygiene) all to itself, and it had "autonomy." The former arrangement, as shown by such eminent physicians and surgeons as Baccelli, Tommasi-Crudeli, and Durante, was vitiated by its detachment from the University. A few years' trial has proved that solidarity with the academic system ensured a more thorough, more enlightened schooling in sanitation and the cognate sciences on which it depends than could be obtained by a separate teaching staff on which these sciences were imperfectly represented or not represented at all. Accordingly, the "scuola d'igiene" has ceased to exist and returns to the University, with all its special laboratories, however, retained. It will, as before, be under the direct cognisance of the Ministry of Public Instruction, like every other branch of medical training and practice. The "autonomy," which made the technical department of the "scuola" a spending department, was also found to work badly. Experts in hygiene, as Baccelli showed, are invaluable as counsellors and assessors, but when it comes to practical administration another set of conditions intervenes for which the laboratory is not the best discipline. They have their place—their indispensable place—in the "Consiglio Superiore di Sanità," but according to the Prime Minister they will no longer have the power of unchecked initiative. Henceforth they will work in concert and, it is believed, in harmony with the heads appointed by the State. These announcements were received by the Chamber of Deputies with loud and well-nigh unanimous expressions of approval.

May 30th.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Alexandria.

DURING the past three weeks cholera has been manifesting itself in a much more businesslike way than at any time since its first appearance last October. The new cases at the beginning of May could be counted daily upon the fingers of one hand, but they gradually increased until they reached 40 on May 12th. Since then the daily returns have only once been higher than 30, but the total number of new cases during the three weeks is 521. The chief centre of the disease seems to have been some outlying hamlets, whence were brought salad and vegetables for town consumption. Directly the disease was stamped out energetically in these hamlets by English inspectors the number of cholera cases in Alexandria began to diminish.

Cholera in Cairo.

With the exception of some half a dozen cases reported during the winter Cairo remained free from cholera until May 9th, when for each of five days there were one or two cases. The disease attacked Old Cairo, the southern port of the city, but it is not certain whether it can have arrived from Alexandria by river or by train. In either case the germs had time to enter the drinking-water of Old Cairo from two men who died on boats there, and this is sufficient cause for the very local distribution of the epidemic so far. Upon May 12th the sanitary department determined to divide the city into districts and to place English medical men temporarily in charge to superintend native medical men and to carry out all necessary prevention work. Old Cairo was allotted to Dr. Keatinge, Saida Zenab to Mr. Milton, the citadel to Dr. Wilson, Ezbekieh to Dr. Engel, Boulak to Dr. Sandwith, while an extra inspector was also appointed to all other districts. Cholera regulations were put into force by the Governor for Cairo on May 16th, and several important measures were also taken for the first time in the history of Cairo. All insanitary bathing-places in mosques were closed, and power was given at discretion to close all dangerous public baths and drinking fountains. In order to preserve as far as possible from contamination the east bank of the Nile above and below the intake of the water company the river has been by the same decree kept clear of all boats and steamers and all washing and other possibilities of pollution. The British soldier is no longer allowed to bathe on that side of the river, and, most important of all, the drainage of the English barracks at Kasr el Nil is no longer allowed to foul the river immediately above the company's intake. It is to be hoped that this last measure will now be permanently adopted, for it has been constantly pressed by sanitary officials, and there can be no legitimate excuse for the negligence of the English military authorities. A special gang of scavengers has been employed to cleanse the river bank, and the whole town is being thoroughly well cleaned up by a special grant of £1500, placed to the credit of Mr. Perry, the head of the scavenging department of the Public Works Ministry. But this sum is only for two months' work, as it is assumed by the financial advisers that when the Nile has risen and cholera has been washed away no urgent need for sanitary matters will exist! It is to be hoped at least that some of the excellent work now being done will be allowed to continue as a permanency. One of the crying needs for Cairo is a real sanitary inspector, who must, of course, be an European. The cholera cases in Cairo since May 9th to May 27th have already numbered 401; nearly all of them so far have been confined to Old Cairo and its neighbourhood. Most of the cases in Boulak have been among workmen employed by day in Old Cairo. The maximum number of cases per day so far has been fifty-three. Dr. Keatinge has a straw hut hospital and a large staff of helpers, including some of the senior students of the medical school, and he has established a simple method of improving the water-supply by running a fire-engine hose out to draw water from a barge far removed from the bank. Yesterday some difficulty arose in consequence of some malcontents objecting to having their possessions disinfected. Unfortunately some women were accidentally sprinkled with acid by a temporary helper and had to be admitted to hospital, but with the exception of this regrettable incident the work has been quite smoothly carried on.

Cholera in other Places.

Since May 20th there have been 60 cholera cases at Tourat, near Cairo, among a new battalion of recruits and the police guarding the convict prison and a great village population of negresses. Coles Pasha, Mr. Crookshank, Surgeon-Colonel Gallwey, and Mr. Littlewood are dealing with this. At Ghizeh, opposite Cairo on the west Nile bank, there have been 22 cases, mostly in the prison. The whole number of cholera cases since October has now reached 2256 and the deaths 1878. This gives the high average of 83 per cent. mortality, but if we assume, as it is only fair to do, that for every reported case there are at least two unreported the average of deaths is lowered at once 27·7 per cent. In considering Egyptian vital statistics it must never be forgotten that the diagnosis is nearly always made by inspection of the dead body by an ignorant native doctor or midwife. The death returns of Cairo are extra high just now, because, in addition to the cholera, there is a fatal epidemic of measles among children under three years of age. The health of the British troops is excellent and the sick-rate at Alexandria, Cairo, and Wady Halfa varies now from 4 to 6 per cent. In spite of this a case of cholera has to-day been reported from the barracks at the citadel. The decoration of C.M.G. recently and worthily bestowed upon Rogers Pasha is the first official reward given by England to the Egyptian Sanitary Department since it came under English control in 1884.

Cairo, May 27th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Regulation of Immigration.

THE immense increase of Italian immigration during the early months of this year is attracting much attention, and the question of refusing entrance to such large numbers of undesirable foreigners is agitating the public. It is estimated that the approximate number of Italians who have arrived in New York between Jan. 1st and April 30th,

Digitized by Google

1896, is 27,000. It is now proposed to apply an educational test. A test of the educational qualifications of immigrants shows that 67·6 per cent. are illiterate—that is, are unable to read or write their own language. It is held that this class is uniformly degraded, ignorant alike of their own language and of any occupation, incapable of appreciating our institutions and standards of living, and hence very difficult of assimilation. The test would be applied at the place where the ticket was bought and by agents of the steamship companies, thus saving the immigrant the hardship of making the voyage in doubt as to his admission or exclusion. This plan would secure rudimentary education on the part of all foreigners applying for naturalisation papers and American citizenship, and thus promote education among those who desire to emigrate.

Colour-blindness in Asiatics.

A surgeon in the United States Navy reports that in Japan among 1200 soldiers 1·58 per cent. were red blind, and 0·833 per cent. green blind. Among 373 boys 1 per cent. were red blind, and among 270 girls 0·4 per cent. Among 596 men in Kyoto 5·45 showed defective colour sense. Dr. Fielde of Swatow, China, examined 1200 Chinese of both sexes, using Thompson's wool tests. Among the 600 men were 19 who were colour-blind, and among 600 women only 1. The percentage of colour-blindness among Chinamen is then about 3 per cent. and does not vary greatly from that in Europeans. Dr. Fielde, however, found that fully half of those tested mixed up blue and green, and this investigator thinks that many of the race are quite blind to the violet colours.

Civil Service Examination for Pathologist.

The New York Civil Service Commission give notice that they will hold an examination for the position of pathologist in the department of public charities. No person shall be admitted as a competitor for appointment who shall not produce to, and leave for a reasonable time with, the Examining Board a diploma or certificate from some reputable institution, showing that he has pursued in such institution, with credit for two years, a course of study adapted to qualify him for the position which he seeks or for which his appointment is desired.

Privileged Communications.

The Medical Society of the District of Columbia has presented to Congress a Bill entitled "A Bill relating to the Testimony of Physicians in the Courts of the District," which is intended to extend to the citizens of this district the privilege of confidential communications to physicians. This Bill is contested by the justices of the Supreme Court of the District of Columbia on the ground of injustice to litigants and as being contrary to public policy to concede the rights of privileged communications to physicians. Twenty States, comprising one-third of the population of this country, have statute laws establishing the inviolability of such communications.

The New York Academy of Medicine.

The New York Academy of Medicine was organised on Jan. 6th, 1847. By bequests, donations, and subscriptions a property has been purchased and a commodious building has been erected, which, including the library, is now valued at $246,292. During the last twenty years the efforts put forth by the academy to collect and maintain a free medical library for the use of the profession and public at large have been more persistent than ever. This library, which at the present time contains more than 4500 volumes, was obtained by gifts, bequests, and purchases, and during the year 1895 was consulted by 6574 readers. Three library funds, by gifts and bequests, have already been instituted and invested on bond and mortgage, aggregating in amount $219,000, the interest of which can only be used for the increase of the library.

Inspection of Bakeries.

It is estimated that there are 2000 bakeries in this city, most of which are located in cellars that were never originally intended for such use and are not only badly ventilated but are the favourite haunts of cockroaches, mice, spiders, and even rats. Coal-dust and other matter float around the places, making them unhealthy as workshops and rendering it altogether impossible that wholesome bread can be produced under such circumstances. Bakeries are often the sleeping place of employés and are not more than six feet from floor to ceiling. As an evidence of the danger of such places some samples of bread from these bakeries have been found to contain thirteen varieties of living micro-organisms. In case of contagious disease among the occupants of these cellars there is no reason why the elements of contagion should not be distributed broadcast through the city in the bread there baked. These shops are to be placed under State supervision.

A National Public Health Service.

At a recent meeting of the American Medical Association the Committee on Public Health reported three methods of establishing a department of public health: (1) to secure legislation depriving the Marine Hospital Service of its public health functions and establishing a new department after the original plan; (2) to accept the Marine Hospital Service as it now exists and attempt nothing further; and (3) to try to improve the Marine Hospital Service, as far, at least, as its public health functions are concerned, and to render it still more effective with more ample powers and a still greater field of activity. The third plan seemed to be the most desirable one, but in carrying it out it was necessary not to interfere with or curtail the powers of the State boards of health. Additional legislation is needed to make the Marine Hospital Service more efficient, and it should be required to act in the several States in coöperation with the State boards of health and not independently of these boards. The association approved of the suggestions and re-appointed the committee with power to secure the proposed legislation.

May 18th.

THE DIFFUSION OF SMALL-POX.—The small-pox data for the four-weekly period ended May 16th show the disease to be still quiescent in London, the notifications in that period having been only 22, and of these 6 were in Kensington—2 of them, however, proving to have been wrongly diagnosed. Thirteen different sanitary areas in the metropolis contributed cases to the total, as against nine districts with 14 notifications in the period of similar duration immediately preceding. In the corresponding period of 1895 the notifications numbered 40 in the whole of London. In the week ended May 23rd of the present year the admissions of small-pox patients to the hospital ships were 5, against 3, 5, and 6 in the three immediately preceding weeks, and last week the admissions were only 3 in number. On Saturday last the patients remaining under treatment numbered 19. Two cases of small-pox have been reported in Birmingham during last week, both having been removed to hospital and every possible precaution taken. Each of the cases has been traced to infection derived from Gloucester. At the latter place in the week ended May 28th the new cases of small-pox coming to light numbered 52, the admissions to hospital 7, discharges 27, and the deaths 19. There was thus a slight increase on the new cases of the previous week. The principal question which has been under discussion at Gloucester lately has been that of the reopening of the schools. These were reopened on Monday of the present week, and the propriety of the order of the town council allowing this procedure has been called in question. The council have required that they may be made aware of all school children who have not been successfully vaccinated, and that such children be excluded from school. The school authorities have demurred to the alleged attempt of the health body to saddle them with the responsibility of ascertaining how far children have been or have not been vaccinated. The council on their part keep the School Board informed of all houses from which children should be debarred from attending school by reason of small-pox occurrences. When the schools were reopened it appears that of 6370 children on the books only 2029 presented themselves, and that only 17 of these were unvaccinated. Some exclusions not called for were recorded, and other children who should have been excluded were reported to be present. There are now only two cases of small-pox at Cheltenham. Leominster is said to have lost some £10,000 on account of three regiments being sent elsewhere which would have been quartered in the town but for the reported presence of small-pox. The report the small-pox had broken out at Tamerton Foliot, near Plymouth, is contradicted, but the disease is stated to have appeared at Pennycross, a village near at hand. At Lancaster 4 cases have occurred, all traced to infection from convalescent cases coming from Gloucester.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

THE summer session of the General Medical Council opened on Tuesday last, June 2nd.

The chamber in which the Council now hold their meetings has been obtained, as the President pointed out, in spite of peculiarly exceptional difficulties, and is now their freehold property. The new chamber has been built over the former room, which was much below the level of the street, but occupies the same space as the old one—viz., about thirty square feet. Light, ventilation, and the heating arrangements seem to be excellent. That the sanitary arrangements are satisfactory should be guaranteed by the fact that they have been carried out under the direction of Mr. Teale and Dr. Thorne Thorne. But although the arrangements were greatly approved the new room was used for the first time under very trying circumstances. The roof is of glass, and the fierce heat of the exceptional sun on Tuesday had free course through it, to the inconvenience of the members of the Council and still more of the visitors in the gallery. Doubtless the ingenuity of the executive committee will devise some means of obviating the inconveniences of this roof at the summer meeting.

No less than three new members were received by Sir Dyce Duckworth, who filled the chair pending the appointment of a President—viz., Sir William Roberts, in place of Dr. Wilks, as representative of the University of London; Mr. W. Thomson of Dublin, in place of Dr. Kidd, as direct representative for Ireland; and Mr. Tichborne, who has been elected to represent the Apothecaries' Hall of Ireland in place of Dr. Moore.

Nothing could be more effective or appropriate than the speech in which Sir William Turner proposed the reappointment of Sir Richard Quain, who, as we anticipated, was selected President of the Council until the expiration of the time for which he was elected Crown representative.

It is the custom of the Council to adjourn at four o'clock on the first day of the meeting in order that the committees may get on with their work, and this was observed on Tuesday. The afternoon was occupied by a carefully written and read speech by Mr. Teale, on the increasing multiplicity of examinations and the increasing proportion of rejections. We publish this speech in full elsewhere and a leading article upon it (pages 1547 and 1573), both of which will, we hope, be read by all who are interested in the subject.

Mr. Teale showed that the examinations had wonderfully increased in number, and he quoted unanswerable evidence to show that there was a serious element of chance in the best of them often telling disastrously on the best men, whose failure was due to brain exhaustion and not to want of knowledge. The constant preparation for examinations interfered with the leisure for work—especially for hospital work, which was now postponed till the later years of the curriculum when many examinations had to be passed—as at the conjoint examination for England the ten minutes' bell and the element of hurry came in to agitate the student. He quoted the testimony of practitioners and on his own experience testified to the fact that some of the best university students were sent out with very little practical knowledge. He pointed out that the fifth year was meant by the Council to be available for pure clinical work either in hospitals or with a general practitioner. But it was largely spoiled for this purpose by the dread of unpractical examinations.

Mr. Teale's motion was seconded by Dr. Pettigrew, and then a series of more or less pertinent criticisms began. Sir William Turner, in his most practical and matter of fact style, objected to the speech as somewhat of an academic performance. This was a curious objection from the representative of an ancient university, where everything is prized according as it is academic. He was a little more forcible when he objected that Mr. Teale's motion was merely declaratory and deficient in point. This defect was soon supplied in the proposal to refer the speech and its material to the Examination Committee to report on at the next session of Council. Our own opinion on the subject will be found in another column.

The whole of Wednesday afternoon was taken up with a debate on the proposal by the representative of the Apothecaries' Hall of Ireland to give examiners in medicine as well as in surgery to the Hall. This appeal to the Council, it will be remembered, is in accordance with the suggestion of the Lords of the Privy Council in their recent hearing of the case of the Hall as affected by the refusal of the Medical Council to appoint surgical examiners in accordance with the provisions of the Medical Act of 1886. The question was one of absolute novelty and of considerable difficulty. There was a sharp division of opinion on the subject among the members of the Council, which was strikingly shown in the discussion. Even Irish opinion was much divided. Sir John Banks seconded the motion of Mr. Tichborne, the representative of the Hall, and it was supported by Sir Philip Smyly, who represents the Royal College of Surgeons. But Mr. Thomson made an excellent maiden speech against the proposal, showing that if the direct representative principle in Ireland does show a wonderful *penchant* for Dublin consultants it has in this case added a member to the Council who will contribute to the value and the dignity of its discussions, and we may assume that Dr. Atthill, who observed an eloquent silence, did not differ much from Mr. Thomson. The opposition to the proposal to accede to the suggestion of the Privy Council found its main exponents in Mr. Bryant, Mr. Wheelhouse, and Sir Dyce Duckworth. On the other side the principal speeches were by Sir Walter Foster, Dr. McVail, and Dr. Heron Watson. The importance of the discussion was in the fact that it involved the attitude of the Council towards the Privy Council in an entirely new situation and one requiring great and mutual respect. The tendency to end a qualifying body whose candidates have dwindled to half a score in the year under adverse criticism is very strong. But it needs to be kept in some check for various reasons. The ending of a medical corporation is a judicial act and has to be performed not by the General Medical Council but by the Privy Council, and it is highly important that in the part which the Council plays in the preliminary process it should act slowly and with something of judicial deliberation. Besides, for good or evil, the Privy Council and the General Medical Council on rare occasions have to coöperate under the Medical Acts. It is highly desirable that they should facilitate each other's work and respect each other's point of view. Opinion seemed very finely divided, but the time for the rising of the Council came. The standing order was suspended to allow Sir William Turner to propose a third course—viz., to postpone an immediate answer to the Privy Council, pending a representation to the Royal College of Surgeons in Ireland and the Apothecaries' Hall of Ireland, that they should make an effort to reconstruct another conjoint board on a new basis satisfactory

Digitized by Google

o the Council. This proposal seemed to commend itself as he best way out of a difficult situation, and Mr. Tichborne vithdrew his motion in its favour. But it came as such a sur-)rise to the ardent opponents of the motion for appointing :xaminers that the discussion had to be adjourned. And so he body concerned remains, and is likely to remain some ime longer, in a state of suspended animation.

TUESDAY, JUNE 2ND.

THE session of the General Council of Medical Education ınd Registration opened to-day in the new hall of the Council n Oxford-street, London. Mr. Wheelhouse, as chairman of he business committee, intimated that the Council were vithout a President, Sir Richard Quain's term of office having :xpired on May 26th, and proposed that in the meantime Sir Dyce Duckworth, senior treasurer and senior officer of the Council, should take the chair and preside over the meeting. This proposal was at once adopted, and Sir Dyce Duckworth took the chair. Mr. Wheelhouse introduced Sir William Roberts as the successor of Dr. Wilks in the representation of the University of London; Sir John Banks introduced Mr. William Thomson as the new direct representative for Ireland in room of the late Dr. Kidd; and Sir John Banks also introduced Mr. Charles R. C. Tichborne, the successor of Dr. Charles F. Moore in the representation of the Apothecaries' Hall of Ireland.

Re-election of Sir Richard Quain as President.

Sir WILLIAM TURNER moved:—

"That Sir Richard Quain, Bart., be re-elected President of the Medical Council till the expiration of the term for which he has been nominated a member of the Council by the Crown."

In putting this motion before the Council he desired, he said, to recall what took place on May 26th, 1891, when Mr. Carter proposed, and he (Sir William Turner) seconded, the election of Sir Richard Quain to the Presidential chair. The services of Sir Richard Quain to the Council dated from 1863, and he was at the time, as he is now, the senior member of the Council. He had taken an active part in its affairs from the time he was first chosen, not only in its general business, but also in certain special duties which had been imposed upon him. The Council had had experience of him as their extremely active and economical treasurer and they had known him as Chairman of the Pharmacopœia Committee. But there were other reasons which weighed at any rate with some of them. They knew Sir Richard Quain as a man abounding in amiability, as one of the most delightful and pleasant of their colleagues, and as a man with an infinite capacity for taking trouble. The Council chose him upon that occasion. Since then they had had five years' experience of him as President, and no one could say that he had shown any want of diligence or ability in the conduct of their affairs. They had to bear in mind that the President's duty was by no means confined to the meetings of the Council. In fact, he was inclined to say that the President's duty and responsibility were in all probability much greater in the intervals between sessions than in the sessions themselves. In explanation of the terms of the motion he had moved he might say that Section 9 of the Medical Act of 1886 laid it down that the Council should elect a president for a term not exceeding five years and not extending beyond the expiration of the term for which the member concerned had been appointed to the Council. He might just add that he knew Sir Richard Quain was extremely anxious to see issued the new edition of the Pharmacopœia. His whole heart had been in the work for so many years, and he knew it would be a matter of great pride and gratification to him if he were in the presidential chair when the new edition was produced.

Mr. WHEELHOUSE seconded the motion.

Sir JOHN BANKS said that Sir Richard Quain was one of his oldest and dearest friends in the world, and he endorsed everything that had been said in his praise.

Mr. BRUDENELL CARTER and Sir PHILIP SMYLY having spoken briefly in support of the motion it was carried by the Council by acclamation.

Sir Richard Quain, who had temporarily retired, was formally introduced to the Council by the mover and seconder, and received a cordial welcome from Sir Dyce Duckworth and the rest of his colleagues when he took the chair.

The PRESIDENT, having thanked the Council for re-electing him, proceeded with the customary inaugural address.

The President's Address.

Sir RICHARD QUAIN, in his opening remarks, expressed his gratification for the honour which the Council had unanimously conferred on him in placing him in his present position on their assembling to-day for the sixtieth session of the Council. He passed in review the great names that had and still continue to be members of the Council and, continuing, said:—

"It is quite true that some things may have been left undone that ought to have been done, and that some things have been done that might have been left undone, or done in a better form; but it must be remembered that the Medical Council is a modern creation, that the laws under which it exists aimed at bringing together a number of elements which had previously had a separate and independent existence, that each of these several elements followed its own traditional method, which it believed to be the best, and that consequently it has taken much time to amalgamate these bodies and to secure that unity which has been most desirable and towards which much progress has been made. In the early days of the Council we had to witness what was described by Sir Dominic Corrigan as 'the battle of the shops'; but few traces of such battles now exist, and I earnestly hope that we have seen the last of them. Difficulties, too, have arisen with regard to the statutes under which we act. There are many members of the profession who think that we should have much larger power than we possess. On the other hand, there are those who think that our powers are all-sufficient and who would resist their extension. My impression is that by patience and perseverance—'moral suasion'—and a steady exercise of the powers which the Council possesses we shall be able to accomplish all that we need or that public opinion would sanction."

[He then referred to the progress and improvement since the early days of the Council in all its proceedings: the advance of medical education and the higher reputation with the public of medical students and medical practitioners. Referring to the incidents of his stewardship since the last meeting of the Council he said:—]

"It may be mentioned that there have been eleven cases of unprofessional conduct inquired into, of which three, together with one that could not be dealt with during the last session of the Council as the matter was being held in a court of law, will be submitted for your consideration. There is also a report of the Dental Committee on the first case of 'covering' by a dental practitioner. Some of these cases are of a very special character and will involve the grave and patient consideration of the Council. Since the last sitting a practitioner at Leeds, whose name was removed from the Register on November 25th, 1887, has been prosecuted and fined for continuing to style himself 'Dr.,' the fine being paid to the Council. A person, without any qualification, styled himself 'Dr. Bell,' practising in London, has been prosecuted for using the titles 'M.D.' and 'Dr. of Medicine,' and fined, the penalties in this instance going to the Receiver of the Metropolitan Police. A penalty, at first retained by the Staffordshire Potteries Stipendiary, has been paid over to the Council as the result of the action of our solicitor. In two other cases conducted by a society, penalties have been recovered, and in one instance remitted to the treasurers of the Council. There have been numerous applications for registration by dentists who failed to register when the Register was open which have been inquired into and reported on by the solicitor. The executive committee will submit a report on the disciplinary functions and penal powers of the licensing bodies, in accordance with the resolution passed by the Council at its last session. The Council will desire to be informed as to our proceedings with reference to the Pharmacopœia. On this subject I can inform the Council that whilst progress has been continuous it necessarily has been slow, in consequence of the great care that is being bestowed upon the work. The pharmacopœia committee, since its appointment, has held several meetings—namely, three in July, 1895, two in November, and two in April, 1896. The subjects which have been brought under consideration have been those relating to the general construction, the omissions and the additions, the weights and measures, nomenclature, dosage, and the classification of the monographs into sections (ten) for revision purposes. Four such sections are in type, two of them having been revised, and two wait revision. This

Digitized by Google

section contains many hundreds of monographs and comprises a large proportion of the work. The committee has already had occasion to invite the assistance of the pharmacological referees, Dr. Lauder Brunton, Dr. Ralph Stockman, and Dr. Walter Smith, and has received valuable information in answer to questions from the committee. The work is not yet sufficiently advanced for the committee to take advantage of the courtesy of the chemical and botanical referees, but as soon as the materials are ready the committee will gladly avail themselves of the services of Professor Thorpe, Professor Tilden, Professor Emerson Reynolds, Dr. Thiselton Dyer, and Mr. Holmes. The Pharmaceutical Society's Pharmacopœia Committee has been engaged more or less continuously in replying to the many questions of the Pharmacopœia Committee of the Council, and has already sent in three reports. The committee has decided to introduce the metric system of weights and measures side by side with the imperial throughout the general text and to employ the metric system alone in the paragraphs relating to analysis. Under present circumstances to forecast the period at which the new Pharmacopœia will be issued is impossible. In the meantime it has been found necessary to order 500 additional copies of the present issue.

"The Council has already been kept fully informed of the steps which have followed the communication to the Privy Council of the Council's refusal to appoint Assistant Examiners in Medicine to the Apothecaries' Hall, Dublin.

"Our legal advisers will report to the Council as to the action which has been taken by the Privy Council in the matter, and an application, which has already been presented by the Apothecaries' Hall in accordance with the suggestion of the Lords of the Council, will come on for early consideration.

"With regard to the important business which now lies before the Council, I may say that, having been just appointed to my present office, I cannot do more than refer to the various valuable reports which have been prepared by the various committees, and which will in due course be submitted to the Council.

"From the Examination Committee we may expect a codification of the Council's recommendations in regard to professional examination, prepared as a result of the recent visitation and inspection of these examinations; from the Education Committee a like report in regard to professional education, another on preliminary education, and possibly reports on minor matters; from the Public Health Committee the report on the Examination for the Diploma of Public Health of the University of Oxford, the last of the cycle of inspections, and a revised table of recommendations; from the Dental Education and Examination Committee a report on an alleged case of laxity in admitting an American dental graduate *sine curriculo* by one of the licensing bodies, remitted to that Committee for report at the last meeting of the Council, and a report by the committee, specially constituted for the purpose, on the so-called midwifery diplomas.

"The last of the dental licensing examinations has just been visited, but as the remarks of the bodies have not yet all been received—indeed there has not been sufficient time—the reports thereon by the Dental Education and Examination Committee will be presented in November."

Referring to the changes in the *personnel* of the Council, Sir RICHARD QUAIN said they missed from amongst them Dr. Kidd, who was always ready to help the Council with words of wisdom emphatically expressed, more especially with reference to educational matters, in which he took very great interest. His place in the Council would be occupied by Mr. William Thomson, who brought to them a very high reputation and special fitness for the duties which he would be called on to perform. They had also been deprived of a most valued member in Dr. Wilks by reason of his elevation to the Presidency of the Royal College of Physicians of London. His place had been filled by the appointment of Sir William Roberts, F.R.S., whose high and special attainments, great ability, sound judgment, and experience could not fail to bring valuable aid to the deliberations of the Council. At the last moment a further vacancy had been created by the resignation of Dr. Charles Moore in consequence of severe domestic sorrow. Dr. Moore's place had been filled by the appointment of Mr. Charles R. C. Tichborne, an eminent chemist and sanitarian, the Governor of the Hall. In conclusion he again thanked them for the distinguished honour which they had conferred upon him, for he regarded the holder of the office of President of the Council, chosen as he is by the representatives of all the educational and licensing authorities, by the representatives of the Crown, and by the direct representatives, as the representative of the medical profession in Great Britain and Ireland.

On the motion of Mr. WHEELHOUSE, seconded by Mr. BRYANT, the President was thanked for his address.

Business Committee.

This committee was constituted as follows—viz., Mr. Wheelhouse (chairman), Sir William Turner, Mr. Bryant, and Dr. William Moore.

Examination Results.

Mr. MILLER, clerk to the Council, presented a series of tables showing the results of professional, preliminary, and other examinations during 1895.

Medical Education and Examination.

Mr. TEALE moved:—

"That the present system of accumulated examinations and the enormous increase in the number of rejections resulting from it are not only unjust to the student, but damaging to medical education; therefore:—That the time has arrived when the General Medical Council should consider:—(*a*) How far examinations and occasions of rejection can be reduced in number; (*b*) how far, whilst maintaining effective examinations in those subjects which it is essential that every medical man should 'know' and 'retain the knowledge of,' it is possible to withdraw from the sphere of public examination several other subjects which it is desirable that every medical man should 'know about,' but with the details of which he need not permanently burden his mind, the 'bird's-eye survey' of such subjects being ensured by compulsory short courses of lectures, with class examination certified by the teacher."

[*We have printed Mr. Teale's eloquent and forcible speech at full length in another place* (p. 1547).]

Dr. PETTIGREW had much pleasure in seconding the motion. The importance of the subject could scarcely be exaggerated. It really raised the whole question of their medical education and examination. He thought the present system had broken down. From the number of rejections one of two things was evident—either that the education of the present day was imperfect or the mode of examination was too high or not adapted to the requirements. He thought the fault was in the system of examination and that they had proof thereof in the enormous number of rejections. He remembered his late master, some twenty years ago, saying to him that there was too much examination and too little education, and really, after all, it was education, and not examination, that made or marred a man. What mattered it to a man how often he had been examined. He was not made a better man thereby. Education should, therefore, be the beginning, middle, and ending in this country. It was the duty of this Medical Council to see that the medical education of the country was conducted on proper lines. It appeared to him that for many years they had been putting the cart before the horse in exalting the examinations and depressing the education. The result of this had been fatal in many ways. Time was when they had originality and power in the imparters of medical education. Now medical education was in the hands of teachers little better than coaches. It was the examination that was leading, not the education; this was bad. Examinations nowadays conduced to a system of cram that was to be deplored. Everyone knew that a smart student might get up sufficiently well in many subjects to pass examinations, but they knew also that he did not know any of them well. He was like a sponge: he took in and gave out, but there was nothing of a permanent character or of individuality about his acquirements. What they had to do was to get the student to understand the subjects he was taught. The present system destroyed the reasoning powers of the student, and when they had finished with him he was a poor creature. Generally he was not a man of thought or resource or a leader of men. They must get their students to think and reflect in order to make them capable. He therefore thought the time had come when the Council should turn over a new leaf. It might suit the convenience of those who were wedded to specialities to advocate the present system, but what he said was this, it was a wrong system and most unfair to the student, who had to pay the penalty as regards time, energy, and money. As to the time allowed for the medical studies of the present day it was notorious that the five years required by the Council were becoming inadequate. He agreed with every word that Mr. Teale had uttered, and he hoped the Council would make his proposal a rallying point, and from

Digitized by Google

this day forth they would make a new departure that would be more fair to the student. He also hoped that the Council would give the subject the most careful consideration and deal with it in the most deliberate manner.

Sir WILLIAM TURNER said that the Council had been favoured with two academic essays—one read and the other spoken. Mr. Teale's reading what he had to say in support of his motion was introducing into the procedure of this Council something quite new. The Council had been accustomed to make speeches—good, bad, or indifferent—but they had not been accustomed to submit essays, and he thought that it was a mistake to make the innovation. But this motion proposed by Mr. Teale was itself a purely academical one. There was not one single practical suggestion in it. Mr. Teale had not even suggested a committee to consider it. He (Sir William Turner) was not in the least degree wishing to throw doubt on the importance of many of the matters that had been brought before them, but owing to the method in which they had been brought forward the Council obtained no practical standpoint for their consideration. The Council as a Council was incompetent to enter into such a discussion as they had been invited to. They had committees, their education and examination committees, and he submitted that the points raised were points which should be submitted to these committees. In conclusion, he submitted that the motion, being purely academical and not practical, there was no use in discussing it.

Dr. LEECH, after a pause, rose and declared that, although he agreed with much that Mr. Teale had said, he could not support the motion. As to the relegation of examinations to the various colleges he could not see that it would be of any service. He should not like to see it carried out because he thought that it would not strengthen education, but would do it harm.

Mr. BRUDENELL CARTER was of opinion that many of the evils complained of would rather tend to remedy themselves in course of time. The great extension of medical teaching and examination in recent years had, he thought, tended to the employment of a larger number of teachers and examiners than were really qualified for what they had to do. The deficiency in the examiners was nowhere more noticeable than in the written questions which were put before candidates. When they got questions written in clear good English they should get candidates who would answer them better. As he could not help thinking they were at the present time in a transition stage he should deprecate any relaxation of the standards that it was the Council's duty to enforce.

Dr. GLOVER said he should be very sorry if the Council came to the conclusion that Mr. Teale had spent an hour too much in the preparation of his statement or a minute too long in its delivery. No man had taken more interest in this subject than Mr. Teale had done, and he should be sorry indeed if the Council dismissed the motion without further consideration. He should suggest that it should be referred to the Examination Committee for consideration and report. It was the Council's business to make education so nearly perfect that the examiners should have less to do, while the proportion of rejections should be far less than it was at the present time. It might not now be a disgrace to be rejected, but rejection all the same was a disaster to a man. Dr. Leech had pointed out that the Preliminary Examination in Arts had not advanced or developed *pari passu* with medical subjects, and he (Dr. Glover) believed that if the Council could make the entrance examinations such as would test men sufficiently they would do the profession and the public much benefit.

Dr. MCVAIL thought that the climax of Mr. Teale's speech came at the end, but in face of the reflection about what medical men of other days would say of medical education in these days it might be an equally fitting subject of speculation to wonder what Stephenson would say if he could look upon the modern locomotive. For his part he was altogether on the side of the moderns in the matter of medical education and examinations. This Council was a council of medical education, but how could it educate except by examining? In his opinion it could only be a council of education by examination. Progress had been made in medical science and education since 1861, and were the public not to get the benefit of it? It was absurd to suppose that the present day requirements could be as easily met as were the requirements of 1861, and they should continue to lay it down that a man must be rejected until he knew the prescribed subject. It was always certainly a serious matter for a student to be rejected, but he thought they had proof in the reports of their inspectors and visitors that the questions at examination were not only fair and suitable, but creditable to those who were responsible for them. It was interesting to hear Mr. Teale. He was to-day a voice from the past, but if this Council gave such an expression of opinion as Mr. Teale hinted at and Dr. Glover demanded they would be doing nothing less than saying that they were to go back in civilisation for half a century.

Mr. WHEELHOUSE wished to call attention to one point which had been made by both inspector and visitor, and that was that so far as this matter of examination was concerned if the Council could devise a means of subdivision of subjects by which a decrease of examinations could be secured, a great deal would be effected. As a visitor himself, he for one had to regret that the examinations had been divided and subdivided until a man lost himself in the multiplicity and did not know whether he was really through when he came to what he thought was the end of the examinations.

Dr. BRUCE regarded the subject of examinations as a very practical one, and on this occasion it had been introduced to the Council by a man than whom there was none in the Council more practical. The Council should see to it that they had a system which would secure the passing of the men best fitted for the profession.

The PRESIDENT thought there was no time remaining for further discussion. There was no doubt that the motion was a declaratory one, and the Council should decide what they should do with it.

Sir WM. TURNER thought that in view of the large amount of business the Council had to dispose of this session, it would be better to proceed to a vote.

Dr. MACALISTER, who was not at all satisfied that there was justification for the presence in the motion of such terms as "enormous increase," "unjust to the student," "damaging to medical education," moved as an amendment, "That the Council, without committing itself in any way to the views expressed in the motion, refer it to the Examination Committee for consideration and report."

Dr. BATTY TUKE formally seconded the amendment.

Mr. TEALE asked if Dr. Pettigrew would accept the amendment.

Dr. PETTIGREW thought it would not be quite fair to dispose of the matter in the rapid manner contemplated. He thought they should adjourn the discussion.

Mr. TEALE, who was willing the matter should go to a vote, briefly replied. He said he felt that he was raising a very, very serious matter, and he had not taken action without much consideration. As to the motion being an academical one, of necessity it must be academical, because it was raising questions that had grown up and were growing. He was not the voice of the past, but rather the voice of the future, for they would find that these questions would continue to grow.

The amendment, having been accepted by the mover and seconder of the motion, was agreed to, and on being put to the Council as a substantive motion was carried.

The Council adjourned.

WEDNESDAY, JUNE 3RD.

The Council met again to-day, with Sir RICHARD QUAIN in the chair.

The Apothecaries' Hall of Ireland.

The entire sitting was devoted to a consideration of the affairs of the Apothecaries' Hall of Ireland and an application by that body for the appointment of examiners in medicine and surgery. The subject was introduced by Mr. MILLER, Clerk to the Council, reading a report of the proceedings in the recent appeal to the Privy Council prepared by Mr. Farrer, the Council's solicitor, and the following application from the Apothecaries' Hall—viz.:—

"Apothecaries' Hall of Ireland,
"40, Mary-street, Dublin,
"May 25th, 1896.

"SIR,—As you are doubtless aware, the question of appointing Assistant Examiners in Surgery for the Examinations of the Apothecaries' Hall of Ireland came before the Privy Council on Monday, 11th inst.

"Towards the close of the argument their Lordships made a suggestion that the Hall should again approach the General Council with a view to the appointment of Examiners not only in Surgery but in Medicine, and should so place themselves in the hands of the General Council to such an extent as would enable that body to be satisfied that

Digitized by Google

the examinations would be for the future a complete and sufficient test for the purposes of the Act of 1886.

"Their Lordships further intimated that in their opinion the proper course would be for the Hall to submit names of proposed Examiners in Medicine for the General Council to approve, and directed the case to stand over to see whether this would be done. The Hall are now prepared to act on this suggestion. They venture respectfully to assure the General Council that their desire is by every means in their power to raise to and maintain at a high level the sufficiency of their Examinations, and they will coöperate with the General Council in taking any steps which are requisite towards that end.

"So far as Medicine is concerned they suggest for consideration the following gentlemen:—

"James Byrne Coleman, M.B, Master in Surgery, Examiner in Medicine, Royal University, Ireland, Physician to Jervis-street Hospital.

"E. B. Townsend, M.B., T.C.D., Professor of Medicine to Queen's College, Cork, Physician to Cork Infirmary.

"*Or*,

"H. Auchinleck, M.D., F.C.S.I., Physician to Mercer's Hospital, Dublin.

"If the Medical Council should prefer to substitute any Examiners in Medicine for those above named, the Apothecaries' Hall of Ireland will be pleased to defer to the wishes of the Council in that respect.

"I have further to ask that the Council will be so good as to appoint the following gentlemen as Assistant Examiners in Surgery:—

"Francis T. Heuston, M.D., R.U.I., F.R.C.S.I., and M.C.R.S.I., Surgeon to the Adelaide Hospital.

"F. Conway Dwyer, M.B., Bac. Surg., T.C.D., Surgeon to Jervis-street Hospital.

"I have not given the names of the examiners whom the Hall will appoint in other subjects, as I do not understand that this is required. Our representative at the Medical Council is, however, furnished with a list of our examiners, and will, if necessary, be prepared to submit them for approval in the same way that I now submit the names of the Examiners in Medicine and Surgery.

"The Apothecaries' Hall of Ireland believe that if the Medical Council will appoint Assistant Examiners in Surgery and Medicine, such examiners will, with the examiners to be appointed by the Hall, constitute an Examining Board who will maintain a standard of efficiency satisfactory to the Medical Council.

"The Apothecaries' Hall have refrained from submitting the names of examiners in other subjects, as they feel that the Medical Council would prefer to be relieved of the responsibility of themselves appointing examiners in any subject in which the Hall are competent to examine without the assistance of the Medical Council. At the same time, if there are any suggestions which the Medical Council think right to make with reference to the examiners to be appointed by the Hall or the examination generally, the Apothecaries' Hall of Ireland will be prepared to adopt them, and have given instructions to their representative on the Council to that effect.

"I am, Sir, your most obedient servant,

"CH. R. C. TICHBORNE, Governor.

"To the President of the General Medical Council."

Mr. TICHBORNE, the new representative of the Apothecaries' Hall, then addressed the Council. He explained that he had drafted the following motion:—

(*a*) "That the application contained in the memorial of May 25th, presented by the Apothecaries' Hall of Ireland to the Medical Council, that the Council should appoint Assistant Examiners in Medicine and Surgery, be agreed to.

(*b*) "That the names of the proposed Examiners in Medicine and Surgery respectively be approved.

(*c*) "Or, if the Council think fit, that any other examiners be appointed in those subjects."

And he proposed now to move the first portion of it. He would not go into the details of the question because they were familiar to the members of the Council. It was stated that the Apothecaries' Hall of Ireland was the oldest examining body in the United Kingdom. He did not say that, but it had been stated by those who had investigated the matter. All he said was that the Hall was a very old corporation and that during the whole period of its existence there was no record of an apothecary having misconducted himself in a professional respect. Besides that they found that they had had connected with them many very eminent men. In fact, the history of chemistry in Ireland was the history of the Apothecaries' Hall. It might be said that that had nothing to do with the question, but that was not his opinion, because they did not find that men held a very distinguished position in their profession, unless their early training had been such as to make them familiar with the subject in which they had particularly excelled. It was an indication that there was sound practical education. He need hardly say that the Hall was very anxious and had done its best to keep up that sound practical education. When the first report appeared containing adverse criticism as to the conducting of the examinations Mr. Chance and himself carefully considered the scheme of the examinations and revised it. They endeavoured to carry out every direction of the Council, and in many cases they went even further than the Council asked them. The scheme was approved by the visitors and inspectors, who in the reports referred to it in the most complimentary manner; therefore, at any rate, their intentions were good. The one weak point, according to the reports, was the examination in medicine, and he thought that logically they had met it. They said: Very well, they were quite ready to be relieved of the responsibility. If the Council would appoint the examiners in medicine they were perfectly agreeable; in fact, they never practically appointed their own men. The men they appointed and who were objected to as regards their examination were appointed, not because they were apothecaries, but because they were clinical physicians holding the highest positions in the hospitals of Dublin. He believed that the function of the Council was to consider the remuneration of the proposed examiners, and they left that entirely in the hands of the Council.

Sir JOHN BANKS in seconding the motion said that he had the most thorough reliance upon the Apothecaries' Hall carrying out what they proposed. He believed that they would raise the standard of education and that they would maintain it. In addition to that he would say that the examiners proposed were all known to him as men of the highest character and he was satisfied that they would do everything in their power to meet all the requirements of the General Medical Council.

Sir PHILIP SMYLY called attention to certain statements made by Sir Robert Reid in the course of the hearing of the appeal before the Privy Council, and complained of their not being justified by the facts. The Royal College of Surgeons in Ireland had never had any voice in the election of examiners in medicine, and they were not therefore responsible in any way for the conduct of the medical part of the examination. These appointments were made solely by the Apothecaries' Hall, who were alone responsible for them. He would ask the Council to remember that by a rule of this body the examiners in medicine of the Apothecaries' Hall must be medical officers of a clinical hospital. That handicapped the Apothecaries' Hall, because they had to take physicians who were hospital physicians. They had no such men in their own body, and they had consequently to go outside. They appointed the best men they could get, and yet after each course of examinations they were remonstrated with because the examination was not sufficient. For this reason, and for this reason alone, the Royal College of Surgeons in Ireland separated from the Apothecaries' Hall. He hoped the Council would consider the matter very carefully, and not wipe out an ancient institution without proper inquiry and investigation.

Mr. BRYANT said he approached this subject with a very great feeling of responsibility. They must all feel that the result of their deliberations would have an important influence not only upon the Apothecaries' Hall as an examining body but upon the power and prestige of the Council. Hitherto the decisions of the Council had received the support of the courts, but here for the moment they had got a little check and they were asked to reconsider an important decision they had arrived at at the last meeting. He asked his colleagues whether anything had been said or done since the meeting which should induce them to alter their decision. When they came to the decision they knew what they were doing. They knew that this examining body had failed on repeated occasions to conduct a satisfactory examination and they knew that the effect of their decision might be to put an end to the Apothecaries' Hall as an examining body. That fact was prominently in their minds at the time. As to the Privy Council, it was evident that they desired to get out of a rather disagreeable and difficult position. He did not think that the Privy Council wished them to be frightened or scared out of their decision. The Council was perfectly free. No pressure had been put upon it; and he hoped that the Council would consider it right to stick to the conclusion at which they had arrived after long discussion and deliberation. If they did not they would seriously jeopardise their own position and would be regarded as incompetent for the discharge of the duties imposed upon them.

Mr. WHEELHOUSE, who was one of the Visitors to the examination of the Hall, said he was surprised to hear Mr. Tichborne speak of the good men who had been connected with the Hall. What atom of educational power did the Hall possess? They had no hospitals, no schools, and no means of teaching surgery, medicine, or midwifery; they had no means of doing anything except examining those persons who had been educated by other people. Therefore if the great men connected with the Hall were of any moment at all it was because they had been thoroughly well educated in other places and not in the Apothecaries' Hall of Ireland. In his visit he had seen the earnest and steady desire to improve the examination on the part of the governing body. He had seen an increasing

Digitized by Google

improvement in the examinations themselves, but he still believed that until the examinations were put upon a higher level than any which he saw they did not reach the level that was reached by almost all, if not all, the other examining bodies in the country.

Mr. TEALE asked Mr. Muir Mackenzie whether, supposing on the passing of the Medical Act of 1886 the Apothecaries' Hall, unable then to join with any other body, had asked the General Medical Council to complete their position by appointing examiners in surgery, the Council would have had the power to refuse the application.

Mr. MUIR MACKENZIE replied that in a certain sense the Council would have had the power to refuse, but refusal in such cases could not be regarded as *bonâ-fide*. In reply to another question Mr. Muir Mackenzie said that the Privy Council had expressed no opinion on the application but simply adjourned its consideration.

Dr. GLOVER said he was one of the minority on the last occasion. He did not believe there was any serious difference between the Privy Council and the General Medical Council and he hoped members would not be led away by any feeling that they were in collision with the Privy Council. He believed that they were in entire concurrence with the Privy Council, the only anxiety of their lordships was that medical matters of this nature should continue to be settled as they had been for the last quarter of a century—by the Council and by the Council alone. He thought that it was unfortunate that the Examination Committee should have suggested that the Royal College of Surgeons in Ireland should separate from the Apothecaries' Hall; such a suggestion was entirely *ultra vires* and had no sanction from the Council.

Sir DYCE DUCKWORTH asked whether the Council did not accept the report of the Examining Committee containing the suggestion and thereby become responsible for it.

Dr. GLOVER said he should be glad to have this most important matter settled.

At the end of a long informal conversation on the point it was announced by Sir William Turner that while the Council dealt with certain specific recommendations in the report they did not formally approve the report.

Dr. GLOVER said he was glad this had been made clear, for the misapprehension had had considerable effect upon the Privy Council. The proposed examiners, he went on to say, would be virtually the examiners of the Council and would conform to their regulations, and in the circumstances he thought the Council would be justified in giving the Apothecaries' Hall another chance.

Mr. WILLIAM THOMSON, the new direct representative for Ireland, said he had given the matter most careful consideration, and had come to the conclusion that in the interests of the public and the profession the application should not be granted.

Sir DYCE DUCKWORTH said that as chairman of the Examination Committee he was fully acquainted with this Irish case, and the story of the Apothecaries' Hall of Ireland was a very old story, for it was a body whose examinations had been declared inadequate twenty years ago. They were asked in the application before the Council to set upon its legs again a body that was certainly crazy. It had been an argument in favour of it that its licentiates served the poorest of the people in Ireland, but on inquiry he found that the poorest class in the country were well provided with medical advice by gentlemen holding the diploma of the Conjoint Board or the triple qualification of Scotland rather than by licentiates of the Apothecaries' Hall. The special necessity for supporting this body therefore disappeared. They had heard a most admirable speech from Mr. Thomson, and if what he said fairly represented the opinion of the profession in Ireland he should like to know what would be the opinion of the profession throughout the kingdom and whether this committee were to sit and consider and endeavour to infuse a new life into this crazy, crumbling body. It must be remembered that the Apothecaries' Hall of Ireland was a body that during the last four years the General Medical Council had condemned utterly. His belief was that the Hall had lived its day and done its work and that the Council ought not in any way to relieve the Privy Council from doing its duty respecting it. He agreed with Mr. Bryant that nothing had occurred in the last six months to alter the opinion they formed last year. There was no occasion for them to do anything. They were not asked by the Privy Council to do anything. The Hall, however, came and said, "Give us examiners." They were asked to prop up this body, which was not worthy on any grounds whatever. They would not be doing their duty to the profession and the public if, for no reason whatever, they should go back upon their former decision and do the dirty work of the Privy Council. Let them show that they were men, not children, that they had the courage of their opinions, and that they would do their plain duty without fear and without favour.

Sir WALTER FOSTER pointed out that for the first time in its history the General Medical Council was face to face in a difficulty with the Privy Council. The point at which they had arrived was one that might lead them into a position which would be one of humiliation and, possibly, of considerable difficulty with reference to all such questions in the future. For himself, he was grateful to the Privy Council for the course they had adopted. In dealing with the case as they had done they had behaved with great discrimination. The Apothecaries' Hall, it must be remembered, was a body which had been recognised by two Acts of Parliament, and placed side by side with all the other licensing bodies in the United Kingdom. While it might have continued an independent existence it had instead followed the direction of the Act of 1886 in seeking combination with the Royal College of Surgeons. For its very virture in so doing were the General Medical Council to say that they would not do for it what they did in 1886? He thought that would be an ungenerous and unjust position to take. It was one he could not vote for, for it would be the suppression by a side issue of one of the licensing bodies maintained by the Act of 1886. If they refused the application that was now before them the case would go back to the Privy Council, and that Council might appoint the examiners asked for. If they did, that would place the General Medical Council in a very unfortunate position, for the examination of the Apothecaries' Hall would be established as a State examination, with all the advantages that the sanction of Royal authority could give it. Moreover, the General Medical Council would have from time to time to report to Parliament how the State was doing its duty as an examining body. They would have the Apothecaries' Hall competing in Dublin with the other bodies, and that he thought would be very undesirable in the interests of the profession. It was unfortunate that they should not have the three licensing bodies in that city forming a joint board. An opportunity to secure combination existed in present circumstances, and before they went back to the Privy Council the General Medical Council ought to try and bring their friends in Dublin together. Rather than give a vote in direct negative of the application, he hoped the Council would find its way out of the difficulty by the adoption of a course that would lead to the creation of a strong combined examining board in Dublin.

Dr. THORNE THORNE was convinced that there was never any want of sympathy with the Apothecaries' Hall of Ireland. The General Medical Council had been very long-suffering with it. Yet the Hall was in the position of being the only body in the United Kingdom that had been reported for inefficiency. That was a very great stigma on its reputation. The decision to refuse appointment of examiners had been very deliberately arrived at, and since it was come to nothing new had emerged. Even the suggestion to appoint examiners in medicine as well as surgery was old and had been deliberately rejected. His impression of the Privy Council's decision was that they did not want in the slightest degree to interfere with the General Medical Council's decision or discretion in the matter, and he believed that if the Council said that they could not change their minds the Privy Council would be absolutely and fully satisfied with what they said. He believed that the Privy Council left the Council's discretion intact. It had been said during the case that one could not help feeling that the General Medical Council were much better judges in this matter than the Privy Council. There was not a suspicion or a hint that the General Medical Council had failed to do their duty. Everything that he had heard had convinced him that the Council were right, and with the testimony of the Privy Council that they had done their duty he saw no reason why the Council should change their opinion.

Professor GAIRDNER did not think the Apothecaries' Hall were justified in asking for examiners in medicine—the subject for which they themselves were responsible. He was

Digitized by Google

against giving them such a prop. It was not in accordance with the spirit of the Act that they should get it. As a matter of fact it would be flying in the face of the Act if the Council were to appoint examiners to supplement deficiency in the subject for which they were legally responsible. He thought that they should tell the Privy Council that it was not within their duty to prop up weak bodies.

Dr. MCVAIL'S view was that the Council was not limited to the appointment of examiners where an independent body could not form a combination with another such body. The Act provided that such examiners should be provided as would make examinations efficient. It might be right that the Hall should cease to be a licensing body, but they should not try to drop it by refusing the present application. Rather let them go to the Government for an Act to get rid of it. He should vote for the motion.

Dr. MACALISTER said that as the Apothecaries' Hall took action under Clause 19 of the Act, they charged the Council with having failed to discharge their duty. But the duty of the Council was to maintain the standard of the examination, and he could not see how that could be done by making appointments on the nomination of the doubtful body. If they were to appoint as desired they would be selecting men who would not only be examiners, but would be inspectors and visitors at the same time, an arrangement that on the face of it was impossible. He thought their answer to the Privy Council must be that they had given that Council's suggestion most careful consideration, but that as its adoption would not enable them to maintain their statutory duty they could not accede to it. If they gave such an answer he thought the Privy Council would have the answer they desired.

Dr. HERON WATSON thought it would be only fair to the Apothecaries' Hall to give their application every consideration. Some of the members of the Privy Council had apparently thought more consideration was necessary.

When Dr. Heron Watson resumed his seat a motion was made for the suspension of the Standing Orders, so as to enable the Council to sit beyond the usual hour of adjournment with the object of finishing the subject under discussion; and in securing assent to it the President mentioned that if the matter was not disposed of to-day it could not be resumed on Thursday, as consideration of penal cases was to proceed on that day.

Sir WILLIAM TURNER would have been pleased if the representative of the Royal College of Surgeons in Ireland could have given the Council some hint that would lead them out of the difficulty they were in. His belief was that it was quite within the power of that College to so reconsider the whole situation that the Conjoint Board for Ireland could be put on a basis which would prove satisfactory. During its brief existence the Conjoint Board had not been on a satisfactory basis, and he thought that that had led to all the difficulties they had had to contend with in this Irish case. It was the opinion that the College had only to look after the matter of surgery and the Apothecaries' Hall that of medicine. That seemed to him to be an absolutely erroneous principle to regulate the functions of the Conjoint Board. What he held was that the partners were equally responsible for efficiency in both subjects. Even at this late stage he had to appeal to Sir Philip Smyly whether it was not possible to arrive at an adjustment on their own side of the Channel. Why should they come to the General Medical Council to have the differences between the bodies adjusted? Or why should they go to the Privy Council? They might with a little sweet reasonableness adjust their differences within their own halls. It would be a very judicious thing if they were to take this matter into consideration, for he must confess that he did not like the position of having to vote for the motion that was before the Council. Yet if he voted against it and it was lost the matter would go back to the Privy Council. He liked that even less, for he should not care to see the Privy Council stepping in and appointing the Examiners in Medicine and Surgery that the Apothecaries' Hall were applying for. It was quite within the bounds of probability that, if the General Medical Council refused, the Privy Council, although knowing nothing about the matter, would appoint. He found that the Privy Council attached great importance to the largeness of the minority on the last vote, and if the minority continued as large was there not the likelihood that they would not hesitate to appoint? Of course, a board appointed by the Privy Council would loom into such importance that the Boards of the Royal Colleges of Physicians and Surgeons would sink into insignificance, and therefore it was a most important question for these bodies whether their action should lead to the creation in Dublin of an examining board with State sanction. As there was no other proposal before the Council if he had to vote he should vote in favour of the motion, little as he liked it.

Mr. BRUDENELL CARTER, as the representative of the Society of Apothecaries of London—the only analogous body represented on the Council—pointed out that it was the opinion of his society that if the Dublin application were refused it would weaken their position. That being so, he had a divided duty on this subject, for if he were influenced solely by what he considered to be the good of the public, he should vote against the motion.

The PRESIDENT thought there was something worthy of consideration in Sir William Turner's suggestion. He should be sorry indeed if the General Medical Council got into difficulty with the Privy Council.

Sir WILLIAM TURNER thought he might venture to propose an amendment to the motion. He moved: "That the Council defers for the present any expression of opinion on the application of the Apothecaries' Hall of Ireland for the appointment of assistant examiners in medicine and surgery, and directs communications to be made to the Apothecaries' Hall of Ireland and the Royal College of Surgeons of Ireland with a view to the reconsideration of their respective positions, so that such a combination may be effected between them as may ensure that an efficient standard of examination will be maintained by the Conjoint Board of Examiners as would be satisfactory to the Medical Council."

This proposal was seconded by Mr. TEALE.

Mr. TICHBORNE asked whether, if the two bodies were to combine, the Medical Council would appoint the examiners.

Sir WILLIAM TURNER replied in the negative. The existing combination between the Irish Surgeons and Apothecaries' Hall would not be at an end for six years, for it would continue in existence for the sake of those who had entered for its diploma previous to the separation in June last. What he would like to see was the strengthening of the combination in such a way as to bring out a mutual sense of responsibility. He thought the Privy Council would be willing to wait to see what might come out of the reconsideration he suggested.

Sir PHILIP SMYLY said the Royal College of Surgeons had given him no instructions on the matter involved in Sir William Turner's suggestion, but from what he knew—and speaking in presence of the President of his College—he could not help feeling that the College separated from the Hall because the former were held responsible when they had no voice whatever as regards medicine. The College would not, he thought, open this question again unless they were to get a very important part in connexion with the appointment of examiners.

Sir WILLIAM TURNER: That is a matter of arrangement between the two bodies.

Dr. MCVAIL suggested that Mr. Tichborne should withdraw his motion in favour of Sir William Turner's proposal.

This suggestion was assented to, and the President was proceeding to put Sir William Turner's proposal to the vote when

Dr. MACALISTER said that he wished to discuss the motion as involving not only the rehabilitation of the Apothecaries' Hall, but a new departure for the Council to make in intervening between two independent licensing bodies.

Dr. LOMBE ATTHILL thought the Council ought to adjourn. The usual hour of sitting had been exceeded, and if they went on discussing the case they might have an all-night sitting.

Dr. MACALISTER moved the adjournment.

Dr. BATTY TUKE seconded.

The Council divided, when there voted for the adjournment 17; against, 10.

The Council accordingly adjourned.

THURSDAY, JUNE 4TH.

The Council met again to-day, Sir RICHARD QUAIN presiding. The first thing done was to pass a new standing order to regulate the procedure in penal cases where a decision is postponed, and, that matter settled, the Council proceeded to adjudicate upon the charges of professional misconduct in the programme of business. Our report of what was done will appear next week.

Medical News.

UNIVERSITY OF LONDON.—The following candidates have passed the M.B. Pass Examination, May, 1896:—

FIRST DIVISION.

Briggs, John Arthur Oswald, St. Bartholomew's Hospital.
Genge, George Gilbert, St. Thomas's Hospital.
Heath, Arthur, St. Bartholomew's Hospital.
Legg, Thomas Percy, St. Bartholomew's Hospital.
Leicester, John Cyril Holdich, B.Sc., University College.
Waldron, Francis Thomas, London Hospital.
Wells, Thomas Henry, Middlesex Hospital.

SECOND DIVISION.

Clough, James Arthur, Leeds Medical School.
Davies, John Edgar Philip, B.Sc., St. Mary's Hospital.
Ducat, Arthur David, St. Bartholomew's Hospital.
Ganner Joseph, Mason College.
Gerrard, Alfred Henry, University College.
Griffiths, John Alban Kendall, University College.
Gullan, Archibald Gordon, University College, Liverpool.
Hibbert, Joseph Coote, University College.
Hugo, James Henry, St. Bartholomew's Hospital.
Instone, Noel, Guy's Hospital.
Johnston, Robert Macfie, University College.
Leon, John Temple, B.Sc., St. Mary's Hospital.
Le Pelley, Amelia Maitland, London School of Medicine for Women.
Lyle, Herbert Willoughby, King's College.
Mackenzie, Rachel Elizabeth W., London School of Medicine for Women.
Maughan, James, Royal Infirmary, Liverpool, and University College, London.
Murray, John Hanna, University College.
Nolan, Harold, Guy's Hospital.
Rait, John Walter Forbes, University College.
Skey, Arthur Richard Harrie, St. Bartholomew's Hospital.
Smith, Graham Udale, King's College Hospital.
Stevenson, Thomas Henry Craig, University College.
Thomas, Evan, University College.
Townend, Richard Hamilton, London Hospital.
Warde, Wilfrid Brougham, St. Bartholomew's Hospital.
Wilson, Francis Kenneth, Westminster Hospital.
Wise, Harry Mortimer, Guy's Hospital.

AN Exhibition of Manufactures, Appliances, nd Inventions for the Saving of Life is to be held at the entral Hall, Holborn, from July 9th to 18th next in aid of ıe Guy's Hospital Fund. Demonstrations by members of ıe St. John Ambulance and the Life-saving Society will be iven and many other attractions will be offered.

LITERARY INTELLIGENCE.—The following are mong the new works announced as nearly ready by Messrs. . & A. Churchill:—"On the Pathology of the Contracted ranular Kidney and the Associated Cardio-Arterial hanges," by Sir George Johnson, M.D., F.R.S, with venty-nine illustrations. "On Gallstones or Cholelithiasis," y Dr. E. M. Brockbank. "A Contribution to the History ! the Respiration of Man," being the Croonian Lectures ır 1895, by Dr. William Marcet, F.R.S., illustrated with agrams (in preparation).

ROYAL MEDICAL BENEVOLENT COLLEGE.—The llowing is a list of the successful candidates at the election ıld on May 29th:—Pensioners: Rhoda H. Bishop (Pugh ınsioner), 9727; Robert Whitby, 4430; Richard D. Larke,)15; Margaret T. Mackenzie, 2421; William Downes, 2396; aroline F. Dain, 2244. Foundation Scholars: Frederick O. eese, 7750; Frank C. Anderson, 6711; Frank S. Cannell, 646; Maurice B. Tribe, 6350; Albert Winter, 5879; Guy . S. Taylor, 5313; T. S. B. F. de Chaumont, 4713; Walter . V. Scott, 4599; Robert H. Hilliard, 4522.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—t a meeting of the Fellows held on Monday, June 1st, for .e election of President, Vice-President, Secretary, and ɔuncil of the College for the ensuing year, the following ɛntlemen were elected:—President: W. M. Thomson, .R.C.S. Vice-President: Kendal Franks, F.R.C.S. Secretary: Sir Charles A. Cameron, F.R.C.S. Council: rchibald H. Jacob, F.R.C.S., Edward Hallaran Bennett, .R.C.S., Henry Gray Croly, F.R.C.S., Sir Philip Crampton nyly, F.R.C.S., Robert Lafayette Swan, F.R.C.S., Sir Wm. okes, F.R.C.S., Henry Rosborough Swanzy, F.R.C.S., Sir ıornley Stoker, F.R.C.S., William Ireland Wheeler, .R.C.S., Austin Meldon, F.R.C.S., D.L., Wm. Carte, .R.C.S., Sir Charles A. Cameron, F.R.C.S., Frederick lcock Nixon, F.R.C.S., Richard D. Purefoy, F.R.C.S., harles Bent Ball, F.R.C.S., Henry Fitzgibbon, F.R.C.S., rthur Henry Benson, F.R.C.S., Francis T. Heuston, .R.C.S., and John Lentaigne, F.R.C.S.

AT the annual general meeting held on Friday, the 29th ult., Sir Arthur Watson, Bart., Q.C., and the Right Hon. A. J. Balfour, M.P., were elected Vice-Presidents of the Royal Medical Benevolent College.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—An ordinary meeting was held on May 15th at King's College, Professor Thane being in the chair. Mr. Keith showed specimens from subjects preserved in formaldehyde which gave rise to a discussion in which the general opinion was that while this substance was very useful for the viscera, it rendered the muscles brittle and easily destroyed. Mr. Keith also demonstrated the relation of the spinal accessory nerve to the jugular vein and transverse process of the atlas, and read a note on the ligamentous bands lying over the infraspinatus muscle. Mr. Hertslet showed two specimens of Rudimentary Ribs on the seventh and eighth vertebræ respectively. Dr. L. Freyberger showed a specimen of Congenital Malformation of the Heart and Thoracic Veins. Professor Wardrop Griffith showed a specimen of Diverticulum of the Larynx and of Fusion of the Occipital Bone with the Atlas. Professor Symington read a paper on the Anatomy of Genu Valgum Adolescentium, and gave a demonstration of sections of the brain of the Echidna. Professor Sherrington gave a lantern demonstration of the Skin Areas supplied by the various Spinal Nerves in Macacus Rhesus. Professor Paterson read a paper on the Cutaneous and Muscular Supply of the Spinal Nerves in Man.

MEDICAL MEN AND FRIENDLY SOCIETIES.—The delegates of the Oddfellows Friendly Society held their annual conference in Bristol last week. At the meeting on May 28th Mr. C. S. Reyworth of Lincoln proposed: "That the Parliamentary agent be instructed to use his best endeavours to obtain a clause in the Friendly Societies Act enabling medical men to take positions as doctors of friendly societies' medical associations without let or hindrance." A long debate followed, and it was alleged that medical men were now starting rival associations and canvassing for members. A delegate, Mr. P. G. Walton, said that in these days they heard a great deal about combination of labour. Were not medical men quite as much justified as any other body of men in combining? Was there any law which would allow trades unions to join together to obtain a certain rate of wages and to deny that right to other classes? It became a fight between themselves and the medical men as to which would obtain the victory. He agreed with a previous speaker that the law of supply and demand would settle the matter. The whole question had been before the Friendly Societies' Conference and a resolution had been passed "that the committee of this conference be requested to consider the present action of the medical profession towards medical societies." The resolution was rejected by 235 to 195, a majority of 40.

DIPHTHERIA IN LONDON.—The prevalence of diphtheria in London during the four weeks ended May 16th was greater than in the four weeks ended April 18th by over 100 notifications. The number in the later period was 890, yielding a weekly average of 222 cases, against an average of 196 in the April period. The deaths were, however, lower—namely, 161 against 183, and the per case mortality was 18·1 as compared with 23·3 per cent. There were four sanitary districts with 50 notifications and upwards, totalling to 283 in all, as compared with three districts totalling to 197; while in the earlier period all save one of the sanitary areas were invaded. The several four-weekly periods up to May 16th have witnessed notifications as follows: 988, 1054, 1009, 785, and 890, and the period in 1895 corresponding to the latter saw 946 notifications. In the week ended May 23rd the deaths from diphtheria in London were as many as 56, as compared with 36, 41, and 43 in the three preceding weeks, and were, moreover, 26 in excess of the corrected average for the twenty-first week of the ten years 1886–95. Last week the deaths fell to 40, but they were still 10 above the average for the corresponding week of the decennium. In the two weeks there occurred 15 deaths in Islington and 13 in Camberwell. Of the total 96 deaths, 89 were of persons aged between one and twenty years. Last week 75 admissions to hospital were notified, against 101, 104, and 99; and on Saturday last there remained under treatment 704 patients. In the fortnight there occurred in Greater London 22 deaths from the disease, and 7 of these belonged to Plaistow registration sub-district.

PRESENTATION TO A MEDICAL PRACTITIONER.—Dr. Henry C. Moore, of Dandenong, Victoria, Australia, where he had practised for upwards of sixteen years, on his leaving was the recipient from the residents of the district of a handsome illuminated address and a purse of sovereigns.

A COMPLIMENT TO A MEDICAL PRACTITIONER.—Mr. Joseph H. Wilson, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., of Warren, New South Wales, was entertained in the Shakespeare Hall by a numerous company of the inhabitants, the Mayor of Warren presiding, at a complimentary evening entertainment prior to his departure for Europe for some time, with the view, however, of returning to permanently reside at Warren.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Public Health (Scotland) Bill.

IT is understood that when the Public Health (Scotland) Bill has been read a second time it will be referred to a Grand Committee mainly composed of Scottish members. If this course be adopted the proceedings, unlike those of the committee of the House of Lords which dealt with the Bill, will be conducted in public.

Poor-law Officers' Superannuation Bill.

When this Bill comes up for consideration on report clauses will be moved extending the scope of the measure to Ireland and providing a system of superannuation for nurses and attendants on the sick in the employment of Poor-law guardians.

Cycling Mishap to a Minister.
